These results are not in accord with recent reports that in folic-acid deficiency choline synthesis from formate or methanol⁶ is decreased. These latter observations are therefore attributable to the known effect of the vitamin at the step leading to serine formation, thus limiting the extent of the subsequent choline synthesis. It is suggested that the well-known synergism between folic acid and vitamin B₁₂ in methyl economy may be explicable on the basis that folic acid inhibits methyl catabolism by better utilization of formate, and that vitamin B₁₂ promotes its anabolism from precursors besides being implicated in the transformation of choline to betaine and to methionine.

This work was aided by a grant from the Indian Council of Medical Research and by gifts of chemicals from Lederle Laboratories, Inc., and Chas. Pfizer and Co., Inc.

The volume of the cells which contained this density of visual pigment was determined in two ways.

(1) Part of the suspension was diluted with saline and spun in a haematocrit tube. The end-organs sank through the diluted sucrose, and the percentage of solid in the suspension could thus be found. It is expressed in col. 6 of the table as the depth of the cell layer (in μ), in the 5-mm. absorption cell.

(2) Several different suspensions were examined under the microscope, and the diameters and lengths of 165 randomly chosen rod cells were measured. The mean volume of a rod (in the suspensions many were incomplete) was found to be 2,114 μ^3 . Samples of the suspensions the visual pigment density of which had been measured were put into Thoma counting chambers. Rod counts were made, in exactly the same way as red cell counts are made. Since the mean rod volume was already known, the percentage of solid in the suspension could be calculated. It is expressed in col. 7 of the table as the depth of the cell-layer (in μ) in the 5-mm. absorption cell.

In the last two columns of the table, the results of all the experiments are brought to a common basis by calculating, in each case, the density of visual pigment per 70 μ of rod-cell. The figure of 70 μ was chosen since, in the frog, the retinal rods are approximately 70 μ long.

Though the density of visual pigment in the suspensions could be measured very accurately, the measurements of the volume of the cells were not precise, and were made by two independent methods in order to examine their reliability. It can be seen that though the results of both methods are com-

parable, the values given by method (1) are slightly lower than for method (2). This might have been expected, since the suspensions contain a small proportion of cells other than rod outer limbs which will be spun down in the haematocrit, but disregarded in the counting method. Moreover, it is difficult not to neglect counting the smaller rod fragments.

Denton has recently measured the density of the visual pigment in the frog retina. In his method, photographs are taken of the rods 'end on'. The density of visual purple was about twice that found in the present experiments (Denton, personal communication). On the other hand, Dartnall's estimate, which was made from the results of measurements on solutions of visual purple, is comparable with the present result².

The difference between Denton's experiments and these is that in the former case the measuring light passed straight down the length of the rod cells, whereas in the suspensions (and in solutions of visual pigment) the rods (or the individual molecules) lie randomly in the absorption cell. The most likely explanation of the difference between the two estimates of the density *in situ* of visual purple in the frog rod is that, inside the end-organ, the pigment molecules are orientated, so that they absorb light most strongly when it passes down the optical axis of the cell, as it does when the retina is in place in the eye.

Spectrum Intensities and Radio Frequency Noise in a d.c. Hydrogen Arc

In the course of experiments involving the use of a d.c. arc in hydrogen as a source for the vacuum ultra-violet¹, it was observed that the arc constituted a powerful source of radio-frequency noise.

To minimize interference with a nearby ionospheric recorder working on 5.8 Mc./s., efforts were made to reduce the noise generation. A shunt capacity of 0.1 μ F. was found to be effective; but its effect on the ultra-violet spectrum was marked. Fig. 1 shows two recordings of the spectrum of the positive column of the discharge in the 1200 Å. region, made with a fluorescence-sensitized photomultiplier, one with an unshunted tube, the other with the shunt. Tube current and gas pressure were the same in each case. The shunt reduced the voltage drop across the tube from 1100 V. to about 750 V. Striations visible without a shunt disappeared when it was inserted. The Balmer lines, especially $H\alpha$, appeared more prominently. The recorded spectra show that the intensities of the molecular lines are reduced by a factor of four or five times, and of the Lyman line at 1215 Å. by a factor of four. The radio-frequency current through the shunt was about 25 per cent of the magnitude of the d.c. arc current.

Fig. 2 shows measurements of the intensity of $L\alpha$, 1215 Å., with various shunt capacities placed across the tube, for different currents and different gas pressures. The arc current density was 4.7 amp./cm.² or a tube current of 150 m.amp. The linear response

Fig. 1. Intensity distribution in hydrogen d.c. arc in the region of $L\alpha$, 1215 Å. Current density 5 amp./cm.²; pressure 0.6 mm. mercury. (a) Unshunted, striated; (b) shunted with 0.1 μ F., no striations.

of the detector was checked by varying the width of the slit in front of the photomultiplier cathode with the spectrograph grating adjusted so that the hydrogen continuum fell on the slit.

Because of the continued decrease in the intensity of $L\alpha$ as the shunt capacity was increased, it was thought worth while to try to estimate the change in noise output at a number of fixed frequencies at the same time. To this end, the standing current in the second detector of a communications receiver was balanced out and a milliammeter inserted to measure signal strength. With the gain control adjusted to keep within the approximately linear range of the detector, a calibration was obtained with a signal generator. The noise signal from the tube was then measured when it was shunted by a number of capacities, between 0.01 μ F. and 0.5 μ F., the aerial being adjusted to bring the received noise signal into the calibrated range with no readjustment of the receiver. This was done for each of five frequency bands, namely, 338 kc./s., 5.6 Mc./s., 9.0 Mc./s., 13.5 Mc./s. and 17.0 Mc./s., with the discharge current equal to 150 m.amp. and the gas

Fig. 2. Intensity of 1215 Å. vs. shunt capacity. The photomultiplier cathode was coated with sodium silicofluoride. The results for $p = 0.75$ mm. mercury correspond to a less efficient coating. $\circ$ — $\circ$, 50 m.amp.; $\times$ — $\times$, 100 m.amp. ($\times 2$); Δ — Δ , 150 m.amp. ($\times 3$). Pressure, 1.0 mm. mercury. $\bullet$ — $\bullet$, 150 m.amp. Pressure, 0.75 mm. mercury.

pressure 0.6, 1.0 and 1.3 mm. mercury. There was a decrease in noise output with increase in shunt capacity, the decrease being most marked for the highest two frequencies.

Since the anode of the tube is near the spectrograph slit, the positive column near the anode contributes most to the intensity of $\lambda 1215$ Å. Instability of the discharge makes observations with reversed polarity difficult; but it appears that when the cathode is nearest the slit the intensity is not very different.

It appears that, together with the disappearance of the striations and a decrease in radio-frequency noise, there is a reduction in the population of electrons having sufficient energy to excite hydrogen atoms. Large numbers of electrons with about 11 volts energy have been found in the striated column², and it is assumed that $\lambda 1215$ Å. results from the excitation of dissociated atoms. The intensity of the molecular lines, which have about the same excitation energy, should then decrease at the same time as the atomic lines. A connexion between the radio-frequency noise intensity and the energy distribution among the electrons, which is strongly suggested by our results, requires further elucidation.

We desire to acknowledge the financial assistance provided by the Research Grants Committee of the University of Western Australia and the help of Miss N. E. White in making some of the measurements. We are also indebted to Dr. R. L. F. Boyd, of University College, London, for discussion of these results.

Shadow Microscopy for Measurement of Height

TOLANSKY has described¹ an elegant method for observing, with a microscope, features of the three-dimensional profiles of particles and other small objects. For a particle of known geometry, it is correct to say that the height can be measured accurately

from the length of a shadow, which may be produced by Tolansky's method or by the usual metal shadow-casting technique. For a particle of irregular shape, however, such as a dust particle, height can only be determined approximately, for the following reasons, which are illustrated in the diagram: (i) the peak may not be in a position to throw the longest shadow; (ii) the plan position of the peak is not known, and consequently neither is that of the base line from which to measure the length of the shadow.

This problem has been investigated on a macroscopic scale, with lumps of coal and smooth weathered stones, 4–8 cm. in size. It was found that the best measure of height is given by $S \sin \theta$, where θ is the shadow angle and S is the distance from the mid-length of a particle, measured in the direction of shadowing, to the tip of the shadow. The percentage standard deviation, σ , of the estimate of height given by $S \sin \theta$ is well represented for both series, over a range of θ from 10° to 30° , by

$$\sigma = 20 (\sin \theta)^{-2.75}.$$

Details of this investigation will be published elsewhere.

Two Half-shade Devices for Optical Polarizing Instruments

THE development of interference microscopes of the double-refracting type has stimulated a renewed interest in eyepieces having at their focal planes sensitive birefringent devices for increasing the accuracy with which forms of polarization can be determined. These devices usually employ a boundary or boundaries formed by one or more birefringent plate elements viewed through an analyser, and the difficulty arises of making boundaries sufficiently precise for the maximum sensitivity to be achieved. The present communication is a brief account of two rather promising solutions to this problem which have recently been investigated here.

In the case of the first and rather more elaborate solution, the boundary is artificially formed by double-refraction of the virtual image of a straight wire located at the focal plane of a positive eyepiece. The double-refraction is adjusted to produce a lateral displacement which is precisely the same as the diameter of the wire, resulting in the formation of a very perfect boundary between the two images of the wire. Since the two images are formed by double-refraction, they are polarized in mutually perpendicular planes and their intensity relationship is therefore a function of the polarization azimuth of the incident light, the intensity ratio being $\cos^2 \theta / \sin^2 \theta$, where θ is the angle which the incident vibration azimuth makes with the vibration direction of one of the two images. An analyser is consequently unessential; but the addition of one, so orientated that its vibration azimuth makes unequal angles with the mutually perpendicular vibration azimuths of the two wire images, results in an enhanced sensitivity which is very approximately proportional to the angular inequality.

The above arrangement seems immediately applicable to polarimetry and similar cases where it is required to determine azimuths of plane polarization; but it can also be applied to double-refracting instruments in which there are two beams polarized in mutually perpendicular planes if these are first circularly polarized by a quarter-wave birefringent retardation plate.

A similar arrangement can also be employed as a simple form of photometric eyepiece for microscopes, because the lateral doubling of the wire image is accompanied by a corresponding doubling of the object image, thus permitting photometric comparison between a sufficiently small isolated feature and its surround. The measurements can be made either by a goniometer-mounted polariser or analyser, using the above mathematical expression.

For applications to such instruments as double-refracting interference microscopes, however, the lateral doubling of the object image can be objectionable, in which case this may be avoided by introducing an initial compensatory form of double-refraction prior to the wire.

A convenient method for obtaining the double-refraction consists in interposing, between the positive eyepiece and the wire, a calcite plate cut parallel to the crystal cleavage. If the plate thickness is chosen to provide a lateral displacement slightly in excess of the diameter of the wire, the two images of the wire can be brought into perfect contact by rotating the plate in relation to the wire. The lateral displacement of such a plate is $0.11t$, where t is the thickness of the plate.

It has proved important to interpose between the plate(s) and the objective a lens to collimate the objective's back focal plane. Failure to take this precaution results in a lateral doubling of the Ramsden disk and consequent intensity variations accompanying the observer's head movements.

The second, and more recent, solution to the same problem was devised with the object of dispensing with double-refracting crystal elements. This is achieved by exploiting the mutually different elliptical polarizations resulting from reflexion at similarly inclined surfaces which are either differently metallized or metallized and total reflecting respectively.

In the preferred scheme, the light to be analysed is obliquely incident upon a dielectric/dielectric surface inclined beyond the critical angle and locally metallized with some such substance as aluminium, rhodium or silver. The unmetallized area then generates the elliptical polarization typical of total dielectric/dielectric reflexion, whereas the metallized area generates a different elliptical polarization typical of the metal employed. The locally metallized surface can therefore be employed as a half-shade device, very precise boundaries between the clear and metallized areas being readily attainable by localized removal of a pre-existing metallic coat. If removal is effected by a photographic etching process, comparatively complex patterns are possible; but, in practice, this is limited by the circumstance that the half-shade surface is steeply sloping and so cannot be focused simultaneously. Straight boundaries and hatches at right-angles to the plane of incidence on the half-shade surface can be satisfactorily obtained by mechanical removal.

A convenient way of applying this reflecting form of half-shade device to a double-refracting interference microscope is to form the localized metallization upon

the totally reflecting face of a normal inclined eyepiece prism and to examine this face through a low-power microscope. The principal plane of the prism should then be orthogonally disposed to the planes in which the two interfering beams are polarized. In the absence of any other suitable form of variable birefringent compensator, the phase angles can be measured by a goniometer-mounted analyser following a quarter-wave retardation plate on the viewing side of the prism.

For applications where the incident light consists of a single beam the polarization azimuth of which has to be measured, it is, of course, necessary to precede the prism with an additional quarter-wave plate the vibration directions of which are diagonally disposed to the principal section of the prism.

It has been found that, if aluminium is employed for the metallization, the coat must be thick enough to be virtually opaque, otherwise there is a strong absorption of one of the two plane-polarized components. On the other hand, rhodium coats have given satisfactory results at a transmission factor as high as 25 per cent for angles of incidence of the order of 45° .

The Kappa Effect

THE new phenomenon in time judgment, described by Cohen, Hansel and Sylvester¹ and called by them the *kappa* effect, is independently confirmed in the following set of observations. These observations have been elicited under different conditions, by another experimental procedure, and over a further range of time-intervals than those described by the above authors.

The experiments were all carried out in daylight or with artificial light. Two 3.5-V. torch bulbs connected to a 2-V. accumulator were set on a table 4 ft. away from, and level with, the table at which the subject sat. These lights were operated by the experimenter so that they flashed at required intervals. The timing was mechanically controlled. The subject was provided with a morse key. The basic procedure was for the subject to reproduce the pause between successive flashes by holding down his morse key. Throughout the entire sequences, the time intervals used were from 7 sec. to 11 sec. inclusive. The mean reproduction time was recorded (1) when a single light, either A or B, was flashed successively, and (2) when two lights, either A then B, or B then A, were flashed. Both conditions were randomized, as well as the intervals themselves. However, the difference between any successive pair of intervals did not exceed 2 sec., so as to minimize any effect due to longer intervals following shorter intervals, or the converse. There were three separate experiments.

Experiment I. The two lights were set horizontally, such that each was equidistant from the subject, with a distance of 32 in. between them. Ten subjects were each given one series of sixty trials. There was a rest pause of five minutes after thirty trials.

Experiment II. Three separate series of measurements were taken at one sitting, with a pause of a

few minutes between the series. Each series consisted of twenty trials, with the lights placed 8 in., 16 in. and 32 in. apart respectively, in that order of presentation. The visual angle approximated to 10°, 20° and 40° for each series, as light A was held constant and light B varied, again in a horizontal direction. Light A was to the subject's left, while light B varied on each series in small steps farther to his right. The 32-in. position was the same as for experiment I. Seven of the previous ten subjects took part.

Experiment III. The two lights were set in line facing the subject; one light was 18 in. above the table and 32 in. behind the other. Eighty readings were taken in one series, a pause of five minutes rest being given after forty readings. In this series the subjects were instructed to fixate a point half-way between the two lights, in order to minimize eye-movements. In this experiment six new subjects were introduced.

The results are given in the accompanying table and graph. They seem to endorse the findings by Cohen *et al.* that a temporal interval between two successive flashes of light will seem longer as the distance between the corresponding flashes increases. The results of the first experiment were subjected to statistical treatment, and show a significant differ-

MEAN REPRODUCTION TIME IN SECONDS

Intervals in sec.	Experiment I 10 subjects	Experiment II 7 subjects	Experiment III 6 subjects
7	I 6.30 II 6.64	8 in. 5.93 16 in. 6.39 32 in. 7.07	I 6.40 II 7.09
8	I 7.13 II 7.44	8 in. 6.50 16 in. 7.15 32 in. 8.06	I 7.38 II 8.16
9	I 7.46 II 8.01	8 in. 7.06 16 in. 7.23 32 in. 8.23	I 7.74 II 8.64
10	I 7.93 II 9.09	8 in. 7.67 16 in. 8.51 32 in. 9.09	I 8.54 II 9.11
11	I 8.96 II 9.51	8 in. 8.39 16 in. 9.11 32 in. 9.49	I 9.04 II 9.71

I, Single light; II, two lights.

ence in the estimations made under the different sets of conditions. In all three experiments the results were unaffected by the order in which the lights were flashed in the vertical or horizontal planes.

The intervals used by Cohen *et al.* ranged from 0.6 sec. to 6.4 sec. They state that within their range the effect tends to diminish as T increases. The undiminished effect here shown to occur with larger intervals may be due to some peculiarity in the phenomenon, or to the fact that the previous experiments were done in the dark, or to other differences in the experimental conditions. Furthermore, in experiments I and III, and in one series of experiment II, the unit of distance was 32 in., whereas in the previous experiments the fixed distance was set at 1 ft.

Cohen, Hansel and Sylvester conclude that "the spatial and temporal components of the space-time events about which judgments are made are psychologically interdependent". That is the conclusion which must obviously be drawn here. However, it might be advantageous to pursue the matter in relation to phenomenological motion. It may well be that, in the kappa phenomenon, an 'imputed motion' is experienced by the subject which influences his temporal judgment.

I am indebted to Mr. B. M. Foss for advice during the experimentation; to Prof. C. A. Mace and Mr. Foss for their assistance with the communication; and to Prof. J. Cohen, of the University of Manchester, for further suggestions.

A Nickel-Gallium Superlattice (Ni₃Ga)

THE nickel-gallium system has been investigated by Hellner¹, who stated that the nickel solid solution extended to 28 atomic per cent gallium, while the lattice parameter increased to 3.591 Å. at the solubility limit. However, in the course of a systematic investigation of nickel alloy lattice parameters, which will be published in due course elsewhere, we have found a Ni₃Ga phase with the Cu₃Au superlattice structure. The nickel-gallium system is similar to the nickel-aluminium system² in that the ordered phase has a relatively small homogeneous range, while on the nickel-rich side a wide heterogeneous range is found at low temperatures, producing a considerable difference of lattice parameter of the two co-existing cubic phases.

A survey of known Ni₃X phases shows that when the radius-ratio ($r_{\text{Ni}}/r_{\text{X}}$) is equal to or less than 1.12, superlattice structures are formed by an ordering of the face-centred cubic nickel solid solution, and the temperature of formation is related to and increases with the radius-ratio.

APPOINTMENTS-VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned.

ASSISTANT LECTURER IN CHEMISTRY—The Registrar, University College, Singleton Park, Swansea (February 27).

METALLOGRAPHER, Experimental or Assistant Experimental Officer grade (with a good basic knowledge of metallurgy) to work on problems arising from research on novel metals and processes—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Berks, quoting 2/103/52 (February 27).

SENIOR LECTURER (with an honours degree in chemistry, and preferably with industrial and teaching experience) in the DEPARTMENT OF CHEMISTRY—The Clerk to the Governing Body, College of Technology, Birmingham (February 27).

ASSISTANT EXPERIMENTAL OFFICER (with a pass degree or at least the general certificate of education to advanced level) in the HYDROLOGY SECTION—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (March 1).

SENIOR LECTURER or LECTURER IN PHYSIOLOGY at the University College of the West Indies—The Secretary, Senate Committee on Higher Education in the Colonies, University of London, Senate House, London, W.C.1 (March 1).

LECTURER in the DEPARTMENT OF CHEMISTRY, Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Wellington, March 5).

LECTURER (with an appropriate honours degree) in AGRICULTURAL ZOOLOGY AND PHYSIOLOGY OF FARM ANIMALS—The Secretary, School of Agriculture, Downing Street, Cambridge (March 5).

UNIVERSITY DEMONSTRATOR (with an honours degree in botany or agricultural botany) in AGRICULTURAL BOTANY, and a UNIVERSITY DEMONSTRATOR (with an honours degree in chemistry or agricultural chemistry, and preferably with experience of soil science) in SOIL SCIENCE—The Secretary, School of Agriculture, Downing Street, Cambridge (March 5).

LECTURER (preferably with special interest in strength of materials) in the DEPARTMENT OF MECHANICAL ENGINEERING—The Registrar, The University, Liverpool (March 6).

LECTURER (with an honours degree in mechanical engineering, and special experience of mechanical engineering drawing and design, theory of machines and strength of materials) in MECHANICAL ENGINEERING, at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, March 7).

SENIOR LECTURER in PATHOLOGY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Sydney, March 7).

ASSISTANT KEEPER (a) (with first- or second-class honours degree or equivalent qualification in engineering or aeronautical science) in the DEPARTMENT OF AERONAUTICS AND SAILING SHIPS; (b) (with first- or second-class honours degree, or equivalent qualification in electrical engineering) in the DEPARTMENT OF ELECTRICAL ENGINEERING AND COMMUNICATIONS, Science Museum, London, S.W.7—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting 8.134/54 (March 11).

ASSISTANT LECTURER (with special qualifications in physical chemistry) in CHEMISTRY—The Registrar, The University, Manchester (March 12).

ASSISTANT EXPERIMENTAL OFFICER (with H.S.C. with science subject as principal subject or equivalent, or higher qualification, and a knowledge of radiography, photography, and photomicrographic apparatus and techniques) at the Ministry of Agriculture and Fisheries Veterinary Laboratory, Weybridge—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A 80/54A (March 13).

CHAIR OF EDUCATION—The Registrar, The University, Sheffield (March 13).

RESEARCH FELLOW IN CHEMISTRY—The Registrar, University College, Singleton Park, Swansea (March 15).

TUTORIAL RESEARCH STUDENTSHIP IN MATHEMATICS (Pure or Applied)—The Principal, Royal Holloway College, Egham, Surrey (March 17).

TUTOR (honours graduate in science) in the DEPARTMENT OF EXTRA-MURAL EDUCATION, University of Glasgow, to conduct and organize classes in adult education—The Director of Extra-Mural Studies, 91 Oakfield Avenue, Glasgow, W.2 (March 20).

LECTURER or ASSISTANT LECTURER in the DEPARTMENT OF BOTANY—The Secretary, University College London, Gower Street, London, W.C.1 (March 31).

SENIOR LECTURER in INORGANIC AND PHYSICAL CHEMISTRY at the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (March 31).

PROFESSORS OF MATHEMATICS, PHYSICS, CHEMISTRY, BOTANY or ZOOLOGY, GEOGRAPHY or GEOLOGY, at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Armidale, April 12).

CHEMIST (with an honours degree in chemistry, and with post-graduate experience in biochemistry)—The Director, Mauritius Sugar Industry Research Institute, Reduit, Mauritius (April 30).

EXPERIMENTAL OFFICERS (with pass degree in physics, mathematics or electrical engineering, H.N.O., or equivalent qualification) and

ASSISTANT EXPERIMENTAL OFFICERS (with G.O.B. at advanced level in appropriate subjects or equivalent) in the Department of Scientific and Industrial Research, Radio Research Station, Slough—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.82/43A.

INTERNATIONAL WOOL SHORTFIBRE RESEARCH SCHOLAR (with qualifications in physical chemistry) for work on research on the structure of the wool fibre—The Principal, Technical College, Bradford.

MASTER TO FRANCH CHEMISTRY to scholarship level—The Master, Marlborough College, Wilts.

SENIOR RESEARCH ASSISTANT (with good honours degree in engineering, practical experience and/or research training) in the DEPARTMENT OF CIVIL AND MECHANICAL ENGINEERING—The Registrar, The University, Nottingham.

LARGE FIRM OF TELECOMMUNICATION
Engineers (East London) require a Junior Capable Engineer. Successful candidate will be involved in the design of capacitors for a wide variety of applications. Ordinary national certificate or Inter B.Sc. in physics or engineering essential. Salary according to age and experience.—Write, giving full details, to Box 846, T. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

GEOPHYSICISTS REQUIRED BY LARGE
firm-wide concern. Applicants must have sound physics degree; subsidiary mathematics d/o or geology is desirable. Age not over 28 attractive salary. When serving overseas free accommodation, or allowance in lieu, medical attention, passages out and home; kit allowance, pension scheme.—Write, stating age, and full details of qualifications and experience, quoting Reference F.107 to Box 1092, c/o 191 Gresham House, E.C.2.

MAJOR OIL COMPANY HAVE A VACANCY
for a Chemist in one of their subsidiary companies Australia. Applicants should be under 35 and be prepared to settle permanently in Australia. They must possess a degree or equivalent qualification in chemistry. Experience in the use of petroleum products and knowledge of test methods essential. Pension scheme. Salary according to age, qualifications and experience. A-class passage to Australia.—Write giving full details, and quoting H 1992, to Box 6555, c/o 191 Gresham House, E.C.2.

GRANTS & SCHOLARSHIPS

ROYAL HOLLOWAY COLLEGE
(UNIVERSITY OF LONDON)
A Tutorial Research Studentship in Mathematics (pure or applied) is offered for the academic year 1954-55, renewable for a second year. The Studentship is intended to enable the holder to gain some experience of university teaching, to work for a higher degree of the University of London, or some other university. Value £20 a year, or £150 with board and residence. Particulars may be obtained from the Principal, Royal Holloway College, Englefield Green, Surrey, to whom applications should be sent as soon as possible, and not later than March 17, 1954.

BRADFORD EDUCATION COMMITTEE

TECHNICAL COLLEGE, BRADFORD
I.W.S. RESEARCH SCHOLARSHIP
Applications are invited for a Research Scholarship provided by the International Wool Secretariat. The Scholarship will be of the value of £350 to £400 per annum, according to qualifications, and will be for work on research on the structure of the wool fibre. Applicants should have qualifications in physical chemistry. Applications should be forwarded as soon as possible to the Principal, Technical College, Bradford.

UNIVERSITY OF LONDON KEDDEY FLETCHER-WARR STUDENTSHIP

The Senate invite applications for the Keddey Fletcher-Warr Studentship for the promotion of postgraduate research in the Faculty of Science. One Studentship of the value of not less than £300 per annum and tenable for three years is offered on the present occasion. The Studentship is open equally to men and women of European descent who are graduates of some British university, or have passed the examination necessary to qualify them for the degree of some British university, but, other things being equal, preference will be given to graduates of the University of London. Applications (on a prescribed form) must be received not later than April 20, 1954.

Application forms and further details may be obtained on application to the Academic Registrar, University of London, The Senate House, W.C.1.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

LONDON, S.W.7
ROYAL DUTCH SHELL STUDENTSHIP IN GEOPHYSICS

This studentship is open to honours graduates in physics or geology (with mathematics and physics at intermediate level) for a two-year course from October, 1954, in geophysical prospecting applied to the search for oil. Value £400 per annum, less fees £60 per annum. Applications must be received before June 1, 1954. Further particulars from Registrar, Imperial College, S.W.7.

UNIVERSITY COLLEGE OF SWANSEA

Applications are invited for a Research Fellowship in Chemistry, of the value of £350 per annum, tenable for two years with the possibility of renewal for a third year. Further particulars may be obtained from the Registrar, University College, Singleton Park, Swansea, to whom applications must be sent by March 15, 1954.

UNIVERSITY OF LONDON

Applications are invited for Imperial Chemical Industries Research Fellowships in Biochemistry, Chemistry, Chemotherapy, Engineering, Metallurgy, Pharmacology, Physics or allied subjects, tenable from October 1, 1954, normally for three years in the first instance. Salary £750 per annum with family allowances and F.S.S.U.

Detailed regulations and application forms can be obtained from Academic Registrar, University of London, Senate House, W.C.1. Applications must be received not later than March 31, 1954.

UNIVERSITY OF LONDON

Applications are invited for Turner and Newall Research Fellowships in Engineering, Inorganic Chemistry, Physics or an allied subject, tenable from October 1, 1954, normally for three years in the first instance. Salary £750 per annum with family allowances and F.S.S.U.

Detailed regulations and application forms can be obtained from the Academic Registrar, University of London, Senate House, W.C.1, and applications must be received not later than March 31, 1954.

FOR SALE AND WANTED

X-RAY SET. NEWTON VICTOR RAYMAX
Rotating Anode Crystallographic Unit, output 50 mA at 90 kV to 85 mA at 50 kV continuous. Designed for all types of crystallographic work, including diffraction, spectroscopy, and structure analysis. Equipment includes two Powder Cameras. New in 1952, and scarcely used since. Write for full details to Box 848, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

THERMOSTATIC WATER-BATH

FOR GENERAL LABORATORY PURPOSES

Maximum temperature 40° C. above ambient,
accuracy of control to within ±0.05° C. (if
higher temperatures are required special
heaters can be supplied to order).

1. Good performance at moderate price.
2. Conforming to modern practice of self-contained units.
3. Silent operation, efficient stirring.
4. Borosilicate glass tank, rim protected by rubber.
5. Good visibility, many applications.
6. Each unit readily cleaned and serviced.
7. Control box for bench or wall fixing.
8. Several accessories for specialised applications.

SATURDAY, FEBRUARY 27, 1954

TWO SHILLINGS

THE *newton*

LONG WORKING DISTANCE ATTACHMENT

... provides a working distance of 12.8 mm. between object glass and specimen when fitted to a standard microscope in conjunction with a conventional 4 or 8 mm. objective.

A further important feature is that the use of this attachment eliminates image reversal and thus further facilitates examination and manipulation of specimens.

The **NEW** Muirhead-Wigan decade oscillator

TYPE D-650-A

THIS precision laboratory oscillator, which covers a range of 1 to 111,100c/s with an overall frequency accuracy of $\pm 0.2\%$ or $\pm 0.5\text{c/s}$, employs the decade tuning system, by means of which the frequency can be set quickly and accurately on four decade dials and a range switch. This system of tuning ensures the highest possible frequency accuracy and stability. It also enables a given frequency setting to be repeated exactly, and permits the addition or subtraction of a fixed number of cycles per second, thus giving an incremental accuracy of an extremely high order. No other type of oscillator possesses all these advantages.

FEATURES

Frequency range: 1-11,110c/s and 10-111,100c/s.

Frequency accuracy: $\pm 0.2\%$ or $\pm 0.5\text{c/s}$.

Hourly frequency stability: $\pm 0.02\%$ over most of range.

Maximum output:

2W Into 8000 ohms above 20c/s.

50mW Into 8000 ohms below 20c/s.

Harmonic content: 1% at 1W output.

Hum level: -80db relative to maximum output at 1000c/s.

Power supply: 200-250V, 50c/s; 90W. or 95-125V, 60c/s; 90W.

Dimensions: $17\frac{1}{2}$ in. wide x $10\frac{1}{2}$ in. high x 13 in. deep.
(43.8 cm x 26.7 cm x 33 cm).

Weight: 83 lb. (38 kg).

SCIENCE IN EDUCATION AND INDUSTRY

RECENT discussions on the shortage of science teachers in schools, and also on the parallel shortage of scientific workers, technologists and technical workers in industry, the research associations and Government experimental stations in Great Britain have produced few positive suggestions to meet the situation. Probably the first step required is to complete the man-power survey which the Advisory Council for Scientific Policy initiated when it appointed its Committee on Scientific Man-power in December 1950, and to concert the policy and action, especially in regard to technological education and the shortage of science teachers, to which its report of March 1952 pointed. Here the Lord President of the Council manifestly has both the responsibility and the opportunity for initiative. To him and to the Chancellor of the Exchequer, rather than to the Minister of Education, we might also reasonably look for efforts to influence the choices which are made of careers by boys and girls at the ages of fifteen or sixteen, or even the subsequent choice of university faculties, including the choice of technology rather than science itself. Drive and imagination are required to arouse the interest of young people, and to overcome the lack of awareness or appreciation of the opportunities and importance of both a scientific and a technical education. These qualities are more likely to be found in quarters fully aware of the vital need for scientists and technologists, and the limitations on progress which their absence must place in every sector of the national economy.

Such measures are essential whatever means are adopted for the expansion of technological and technical education. Although an improvement in the supply of science teachers in the schools would help, it is not by itself likely to ensure that there are no places in the existing schools of science, engineering and other technologies unfilled for lack of well-qualified applicants, much more in the expanded schools which are so clearly desirable. Moreover, such measures merge almost imperceptibly into those required for determining the wisest deployment of our scientific and technical man-power, on which the inquiry already suggested could throw further light.

The shortage of science teachers of high quality is in fact only one, though perhaps the most critical and prominent, of our failures to secure the most effective deployment of our scientific man-power. The realization of the threat that this shortage offers to our national welfare should lead to much more drastic and far-reaching action than that contemplated in the report from the National Advisory Council on the Training and Supply of Teachers. It is right and necessary that all possible measures should be taken not only in the schools, but also in the universities, in industry and in Government departments, to see that trained scientists are not employed on duties for which less highly trained men or women are competent, as it is also to see that their services and

advice are not wasted by managements or administrators incapable of assessing scientific and technical factors in a situation. But inquiry should go further into the real reasons for the shortage.

Apart from the economic reasons, the stress which is now being laid on the importance of opportunities for research in schools lends some support to a recent suggestion of Mr. Eric James, High Master of the Manchester Grammar School, that we have invested research with a prestige which is destructively high, since it may be attracting all the ablest scientists from the task of educating the next generation of investigators. Whether or not that view be correct, that it should be advanced suggests caution in dealing with the situation on purely economic grounds. If purely financial proposals could be found which did not involve awkward repercussions, they might still offer no complete solution by themselves. Even diagnosis is as yet incomplete, and meanwhile energetic action along all possible lines to alleviate the situation, including grappling with the thorny question of retirement, is imperative.

Neither that action, nor the working out on the basis of further inquiry of the long-range solution to deal with real causes, can be left to the Minister of Education. Moreover, there is linked with it the whole question of the nature of science teaching in the schools and the use to be made of science graduates as teachers. If more of the graduates in arts, for example, left the universities of Britain with some sound knowledge of general science, they might well be qualified to assist in the general science teaching which is so desirable for the ordinary citizen, whether or not he proceeds beyond the grammar school or technical school level. That in itself, by facilitating the absorption of science into the general culture, should tend to further the supply of promising students for the technical colleges and the university schools of science or technology, and it should also assist the graduate science teachers to concentrate more on the sixth forms or the teaching of those with a scientific career in mind.

No more need be said here to illustrate the complexity of the relations in these questions of training and deploying our scientific and technical manpower, and the imperative need not merely for more precise information but still more for close co-ordination between all the Ministries concerned and between industry, the universities, the technical colleges and the schools. Much more clear thinking is required about the respective functions of these institutions. Although the nature of professional training and the place where it should be given—or at any rate completed—may not be susceptible of a general interpretation, at least ideas could be formulated clearly enough for some agreement to be reached between, say, the universities, the colleges of technology, the research associations, and professional institutions in regard to a particular industry, which would permit expansion being planned on a rational and a national basis. The universities, too, play a decisive part in determining the use made of science teachers in the schools, and a constructive approach from them, as the Advisory Council on the Training and

Supply of Teachers obviously recognizes, could have a decisive influence in improving the situation.

Finally, as has already been indicated, the supply of man-power cannot be considered apart from its deployment. The nature of that deployment can markedly affect the resources available for training, as can be seen, for example, in the concern freely expressed by the universities, both in the United Kingdom and in the United States, regarding the sponsoring of research by Government departments. Clearly, the universities would be quite right to set a strict limit to the research enterprises, even in fundamental science, for which they accept responsibility even at Government behest, both because of possible adverse effects on their teaching responsibilities and because the balance of research effort may be seriously distorted. Moreover, while the possibilities in the way of research at the higher technological institutions or of technical colleges have scarcely been explored, there are limits to what is possible here, and the final word must rest with the institutions themselves. A sound judgment would almost certainly be facilitated by the advice and help which the University Grants Committee, or a technological education sub-committee of that body, could give. The complexity of all these relations is sufficient reason for urging once again the importance of placing the responsibility for higher technological education in the hands of the same body that bears the responsibility for the broad supervision of university education.

The question of technical education and of the technical colleges would still remain. While that should no longer be the responsibility of the Ministry of Education or of the local education authorities, it is less clear where the responsibility should be placed. Apart from the educational responsibilities of the research associations, the increasing importance of association of industry with technical education lends support to the view that the Department of Scientific and Industrial Research should be more closely associated with technical education itself. The view which the Advisory Council for Scientific Policy has taken of its responsibilities towards industry and towards education suggests that that body might possibly prove the appropriate authority for watching over the development of the technical colleges in the interests of the nation.

The importance of securing closer association of industry in all these developments can scarcely be over-stressed. It is already fully recognized by the Advisory Council for Scientific Policy, no less than by that for Scientific and Industrial Research, that the effective utilization in industry of existing knowledge, let alone the wider prosecution of industrial research, depends on the presence in industry, and especially at the management-level, of those capable of appreciating the significance of scientific work and the bearing of particular advances on their own industrial activities. This is not simply a matter of education for management: it is a matter of technical and scientific education, of providing industry—and especially the smaller firms—not so much with first-class technologists, as with the larger

numbers of technicians and craftsmen, of men and women trained to a level which enables them to carry out competently the manifold tasks in industry for which a less rigorous training in science and technology is entirely adequate. The problem is not one of producing more scientists or technologists of the very highest class, but of training in science and technology many more of the ordinary school-leavers who could profit by such training though not necessarily to honours degree level.

There is a further reason for welcoming closer association with industry. Developments like these which promote the right balance between technical, technological and university education in the light of the known needs of industry in Great Britain should also foster the spirit of enterprise within industry, without which development may well be sterile. The warning which Sir Henry Tizard gave in his Messel Memorial Lecture on this point needs to be remembered. While the Government is justified in extending the life of the National Research Corporation for a further five years, the latest report of the Corporation gives no clear evidence as to the permanent value of the Corporation in industrial development. At least it can be said it will not be healthy if the existence of the Corporation encourages industry to leave to Government departments judgments and decisions for enterprises in which the initiative properly rests with industry itself. Nor should it be thought that resistance to increased industrial efficiency and productivity comes solely from the management level of industry; for the Labour Party recently attempted to write into the Iron and Steel Bill a provision that no change in the technique or geographical pattern of industry should be allowed if it renders any workers redundant, or down-grades their job or causes them to move to a new locality.

The bearing of technical education, and indeed of the content of general education, on technological change and productivity, so well brought out in the reports issued by the United Nations Educational, Scientific and Cultural Organization, could scarcely be better emphasized. While, therefore, the Government's new policy towards the Department of Scientific and Industrial Research, like the new arrangements for the development of atomic energy, promises substantial benefit to Britain's economy, the realization of that promise depends on wider considerations. It depends in the first place on the Government utilizing the opportunities thus afforded to concert a real policy for scientific and industrial development, and especially for scientific and technical man-power. Of the many facets of that policy, none is at present more important than the handling with vision, with energy and decision, those questions of the supply of science teachers and the balance of technical, technological and university education. Nor will it suffice to secure adequate numbers of scientists, technologists, technicians and craftsmen, managers and administrators capable of identifying the problems to which scientific or technical knowledge can contribute, of assessing the scientific and technical aspects of a situation, and of appreciating

the significance of new knowledge. To secure the full and efficient use of such men in industry, Government establishments or public bodies, involves not only eradicating the idea that scientists and technologists must always remain such and be debarred from managerial responsibility; it may well involve also a new outlook and attitude in the Government and in industry at all levels, such as can come not simply by encouraging more people to take up scientific studies, but by a radical change in the content of general education and the teaching of science.

AFRICA SURVEYED

Africa

A Study in Tropical Development. By Prof. L. Dudley Stamp. Pp. vii+568. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953.) 68s. net.

PROF. DUDLEY STAMP fears that people "full of enthusiasm but lacking both knowledge and wisdom" will rush in to the salvation of tropical Africa: and so he has attempted, dispassionately and objectively, "to consider its geographical background as an environment for human activity and to study the responses which have been evoked from its African inhabitants and those who, in the last few centuries, have penetrated its fastnesses and molded its fortunes". His special concern has been to emphasize those physical facts of the environment which exercise a permanent and continuing influence and to concentrate more upon major problems than upon local details.

British readers must remember that the book is meant primarily for an American public. This helps to explain not only the high cost of the volume and the excellent range and quality of its 234 illustrations, but also the statement on the dust-cover that "America has a very special interest in Africa" and the fact that as many words are devoted to Liberia as to the larger and more populated territories of Kenya or Uganda.

The volume is divided into three parts: "The Continent"; "The Countries and Regions"; and "Africa Today". Two hundred pages are given to the first section on the whole continent; about three hundred to the regions, of which Prof. Stamp recognizes ten; the final section is but a brief and disappointing chapter incorporating some recent bibliographical and statistical information.

In the first part, Prof. Stamp has conveniently brought together much that is common knowledge about the opening-up of Africa and its human and physical geography, and has illustrated it by a valuable series of maps and diagrams. He has, moreover, incorporated much that is new, notably in the chapters on climates and soils, while in the chapters on pests and diseases and on transportation he has dealt with subjects that in Africa have too often been inadequately considered.

The regional chapters begin with a reminder that "nearly every country in the world has its own individuality". It is expecting much of any writer (even though he be of Prof. Stamp's eminence) to convey in words, diagrams and photographs what a famous French geographer called 'the personality of regions'; the more so in a land-mass as vast and as politically diverse as the continent of Africa. Inevit-

ably a great deal of the information must come from secondary sources and should be acquired and sorted over a longer period than the author has been able to devote to the preparation of this volume. Prof. Stamp is much more convincing when he writes of what he knows at first-hand—Nigeria, for example, or the Union of South Africa—than when he is dealing with certain other areas where the facts seem unrelated and where there is no proper emphasis on the special problems of the moment. In places the juxtaposition of the generalized and the detailed is confusing. In the chapter on East Africa, for example, a general map with relief and place-names (inferior to many atlas maps) and a crude map of population distribution (with 10,000 persons represented by a single dot) are placed alongside reproductions of excellent previously published maps of the topography and vegetation of Mount Kilimanjaro and of types of land occupation in Tanganyika Territory.

Geographers rightly emphasize that their prime concern is with regions as they are: but in a continent the political and economic future of which is of such consequence to the rest of the world, might not more space be devoted to a consideration of some of the prospects of to-morrow? For example, what is Prof. Stamp's assessment of the possibilities of industrial development in the Rhodesias if the water-power of the Kafue river or at the Kariba gorge is harnessed? How will the dams at the Owen Falls in Uganda or on the Volta in the Gold Coast affect the economies and the peoples of East and West Africa, respectively? This book gives no real answer to questions such as these. On the other hand, extended comments are given on development schemes that have proved unsuccessful, notably the East African groundnut scheme, though not everyone will accept all that Prof. Stamp has written about the reasons for its failure. There is, unfortunately, nothing on the geographical and economic background to Central African Federation, nor of the difficulties that geography presents to the proponents of *apartheid* in the Union of South Africa.

But to emphasize such inadequacies and omissions as there are, or to refer to any errors of fact or shortcomings of style that an individual reader may note, would be ungenerous of a fellow-geographer who is impressed by Prof. Stamp's amazing capacity for the condensation and collation of so much information of a highly diverse, and sometimes technical, nature into a reasonable compass. For all its 568 pages, this is a short book compared with other comprehensive volumes on Africa, such as Lord Hailey's "African Survey" (1,837 pages) and the same author's "Native Administration in the British African Territories", the five volumes of which contain nearly 1,400 pages. Prof. Stamp does not claim originality for his latest book: it is essentially a compilation in which attention is very properly directed towards many recent papers in geographical and other periodical literature. For geographers who find it hard to keep afloat in this gathering spate, the book will be invaluable: indeed, for all concerned with Africa, it will become a most useful work of reference. It will do good because it reminds us, as Prof. Stamp puts it, that "throughout much of Africa, especially tropical Africa, the course of man's life is still dictated in large measure by the physical environment". It challenges us all to an investigation of the many problems of Africa to-day on the broadest possible basis, both scientific and political.

R. W. STEARL

NATURALLY OCCURRING DERIVATIVES OF NAPHTHALENE

Elsevier's Encyclopædia of Organic Chemistry
Edited by F. Radt. Series 3: Carboisocyclic Compounds. Vol. 12B: Naphthalene, A. No. 5: Compounds containing One Naphthalene Nucleus; Naphthoquinones and other Polyketohydronaphthalenes; pp. xxx+2717-3260+Ind. 44; £19. No. 6: Compounds containing One Naphthalene Nucleus, Carboxylic Acids (CO₂H in Side Chain); pp. xlviii+3261-3964+Ind. 78; £24 10s.

(Amsterdam and New York: Elsevier Publishing Co., Inc.; London: Cleaver-Hume Press, Ltd., 1952-53.)

THE compilation of Vol. 12B of this work, dealing with naphthalene and its derivatives, is proving an exceedingly formidable task. Section A, comprising compounds containing one naphthalene nucleus, has not yet been completed, although, with the two parts now under review, six parts have been issued, with nearly four thousand pages.

The first of the two parts (No. 5) is concerned largely with the naphthoquinones and their functional derivatives, their homologues, halogen derivatives, nitro-, amino- and azo-derivatives, followed by a large section which describes in detail the hydroxy-naphthoquinones and their derivatives. To the natural-product chemist the latter section is the more interesting, dealing as it does with natural pigments including lawsone, juglone, phthiocol, plumbagin, shikonin and alkannin, Hooker's lapachol, and the very remarkable echinochromes and spinochromes. Echinochrome A is said to activate the sperms of sea-urchins in a concentration of 1 in 2.5×10^5 , which probably represents the highest dilution in which any form of biological activity has been observed. Physiological properties are described for quite a number of substances listed in both parts of Vol. 12B, and in the case of the naphthoquinone derivatives there is frequent reference to their use in analytical chemistry. A ten-page section discusses compounds with vitamin K activity. The reactions of the quinones include many leading to complex heterocyclic structures, which are formulated. 4-Benzyl-1:2-naphthoquinone is one of the few *ortho* quinones which have been used successfully in the Diels-Alder reaction. A few synthetic dyes are described, such as α -naphthol blue, naphthazarin and naphthopurpurin, but the bibliographies contain no reference to patent specifications. Most of the quinones treated are derived from 1:2- or 1:4-naphthoquinones; there is a brief description of 2:6-naphthoquinone, and a short section dealing with diquinones (1:2:3:4- and 1:4:5:8-). Hydronaphthalenes are represented by their few known polycarbonyl derivatives.

The second part (No. 6), in a sense, is not concerned with naphthalene chemistry at all, as it deals with open-chain carboxylic acids which happen to have naphthyl or substituted naphthyl substituents. Associated hydronaphthyl carboxylic acids are also treated. Carboxylic acid derivatives, for example, nitriles and amides, are included although the derived acid may be unknown. Lactones are described, in spite of their heterocyclic character, even if the related hydroxy-acids are unknown. Naphthoic acids and their derivatives will doubtless be dealt with in the next part. The majority of the acids included in the present part are monocarboxylic acids; but brief

sections describe also some di-, tri- and tetra-carboxylic acids. The most important natural product treated is *santonin*, and the section which describes this lactone and its derivatives and transformation products amounts to more than a hundred pages. *Artemisin* and *alantolactone* are dealt with in some detail, and it is a little inconsistent that *pseudosantonin* is dismissed in a dozen lines. The reason is that its structure was unknown when the material was assembled for this part.

The features with which users of the "Encyclopedia" are already familiar are found again in both parts. There are the usual clear type and excellent printing, the editorial footnotes commenting on ambiguities or wrong assignments of structure (in one case, attention is directed to the fact that the analysis figures do not fit the proposed formula), the elaborate reaction schemes showing the interrelationships of complex natural products (for example, *juglone*, *lapachol*, *santonin* and *artemisin*), and the inclusion of completely up-to-date references to important papers giving structural information. There is comprehensive literature cover up to 1944. A useful feature is the indexing under specific headings of anthelmintic and growth-promoting compounds (for example, 1-naphthylacetic acid) and natural products.

The high standard of production has been well maintained, and organic chemists will be grateful to the Elsevier editorial staff for this further contribution to the bibliography of organic chemistry.

J. W. COOK

NUCLEAR PULSE AMPLIFIERS

Signal, Noise and Resolution in Nuclear Counter Amplifiers

By A. B. Gillespie. (Electronics and Waves Series.) Pp. xii+155. (London: Pergamon Press, Ltd., 1953.) 21s.

AS its title implies, this book does not attempt to deal exhaustively with the design of amplifiers for use with nuclear counters, but restricts itself to some important features in which such amplifiers differ from those used in other applications. These differences arise mainly from the fact that a nuclear counter amplifier receives its input signal in the form of a charge and delivers a pulse of which the peak amplitude must be linearly related to the magnitude of this charge, but the shape is of little interest.

In practice the shape and duration of the output pulse is determined almost entirely by the amplifier constants and scarcely at all by the input signal. The signals usually occur at random times, so that it is not possible to resort to some of the methods for improving the signal-to-noise ratio which are employed in the radar field.

After a brief introduction, the author discusses, in elementary fashion, the nature of the signal produced by an ionization chamber and the relation between this and the amplifier time-constants. The next section discusses the various sources of noise in the amplifier and how these depend on circuit design and valve-operating conditions. This is followed by a detailed discussion of signal-to-noise ratio and how this is influenced by the amplifier parameters. The important point is made that usually a compromise must be sought between

signal-to-noise ratio and time resolution. Thus, in comparing the signal-to-noise ratios provided by different systems, the results will be misleading unless the time resolution of these systems is also taken into account. This has not been appreciated by some earlier writers. The next section shows how amplifier noise affects the accuracy of counting experiments. Finally, proportional counters and scintillation counters are considered. In these cases amplifier noise is seldom a problem; but similar effects may be produced by a background of unwanted radiation reaching the counter. Theoretical treatment of this presents difficulties which the author has not been completely successful in overcoming, but useful data are presented.

There is a danger that a book of this nature may become excessively mathematical. This has been successfully avoided by the author, who banishes most of the mathematics to the appendix and relies on physical arguments supported where necessary by theoretical and experimental results. As a result, the text is lucid and easy to read, though one or two grammatical lapses can be detected.

One may question the author's wisdom in taking into account at the outset the finite time of rise of the ionization-chamber pulse. This leads to rather complex expressions in the early part of the book. It might have been simpler initially to assume a step-function input signal and to have derived expressions for signal-to-noise ratio on this basis. It would then not be difficult to show how these results are modified in cases where the pulse-rise time is not short compared with the amplifier time-constants.

Because of its mathematical and practical simplicity, the author has given most consideration to the case where the upper and lower limits of the amplifier pass-band are determined by single resistance-capacity time-constants having values T_1 and T_2 respectively. He rightly concludes that for best results $T_1 = T_2$. These calculations assume that all the other time-constants limiting the high-frequency response of the amplifier are short compared with T_2 , and it might be inferred that this is a necessary condition for best signal-to-noise ratio. This is not the case, for it can be shown that if the upper-frequency limit is determined by many time-constants all equal to T_2 , the signal-to-noise ratio for a given resolution time, far from being worse, is actually slightly improved. Thus, in an amplifier in which T_1 and T_2 are made adjustable, the most economical design is one in which the high-frequency time-constants of all the stages are equal to the smallest desired value of T_1 .

The deliberately limited scope of the book excludes a good deal of information which would be of value to the designer of nuclear counter amplifiers, such as the choice of the most suitable type of negative-feedback circuit and its design to give stable gain with a monotonic step-function response while making best use of the gain band-width properties of available valves. The reaction of pulse amplifiers to large overload pulses is also of importance. While a fair amount has already been written on these subjects, the last word has yet to be said.

Within its scope, however, the book is an excellent one and contains many theoretical and experimental results which have not previously been published. The agreement shown between theory and practice is, in most cases, remarkable. This is a tribute not only to the author's theoretical analysis, but also

to the skill and care with which the experimental measurements of noise must have been made. To obtain reproducible results from such measurements, especially at low frequencies, is something of an achievement.

The designer of nuclear pulse amplifiers will find the book valuable, if he accepts the fact that the problems considered are by no means the only ones he will encounter. The book will also be helpful to nuclear physicists and others who may have to undertake experiments the success or accuracy of which is threatened by the presence of noise or background radiation.

E. H. COOKE-YARBOROUGH

HISTORY OF SCIENCE

A History of the Sciences

Main Currents of Scientific Thought. By Dr. S. F. Mason. Pp. viii+520. (London: Routledge and Kegan Paul, Ltd., 1953.) 28s. net.

NO one can to-day lament a deficiency of general histories of science. Dr. Charles Singer's "Short History" and Sir William Dampier's "History" were early efforts in this field, of which new editions are still in demand. Dr. W. P. D. Wightman's "Growth of Scientific Thought" is a more recent endeavour to cover similar ground, and now there is this fresh survey from Dr. S. F. Mason, of Oxford, which extends from the ancient empires to Lysenko. This is longer, and more complete in factual detail (especially for the modern period), than any of its predecessors, and on many points the structure of the book shows, very properly, the influence of important modern investigations. The indebtedness of Hellenistic science to its precursors among the Egyptians and Babylonians, as well as among the pre-Socratic Greeks, is well brought out. China and India form the subject of separate chapters in which their contributions to the West are analysed. These are important additions to a general history of science; but they are not without corresponding losses, since Islam is dismissed in six and a half pages, and medieval Europe in sixteen. Dr. Mason then devotes about two hundred and ten pages to the period 1500-1800, in which the extent to which the 'mechanical philosophy' permeated scientific thought is rightly emphasized, and slightly less space to the nineteenth and twentieth centuries. The main criticism of this balance of the attention given to the main stages of scientific development concerns the very recent period, for here Dr. Mason might be judged to linger excessively on topics which have been dealt with already in a multitude of publications.

On other points, however, Dr. Mason adopts a more conservative attitude. It is a little surprising to be told that Aristotle's zoological works are of later date than his physical (p. 31); that "medieval craftsmen contributed the experimental criterion to the scientific method" (p. 95); that Boyle "gave the modern definition of a chemical element" (p. 190); and that "When natural philosophy began to show signs of stagnation towards the end of the seventeenth century the nascent science of chemistry suffered a serious reverse" (p. 241). On this last question especially, the complete omission of the fundamental work of Mme. Metcalf from the bibliography is surely significant. But generally the author proves himself

well acquainted with the present flood of research on the history of science—though he lists few non-English publications.

This has helped him to build up a detailed story, especially from the sixteenth century onwards—that is, about four-fifths of the volume. He has assembled a much greater wealth of information on many subjects (for example, science and religion at the time of the Reformation; embryology; and the cell-theory) than is available in any comparable book. To have done so is probably its highest merit, and it is regrettable that the entire lack of illustration must render some of the material unintelligible to readers to whom such matters are unfamiliar. Illustrations would inevitably have increased a very moderate price; but they are ill spared. History, however, is not simply information; the facts must be interpreted. A single theme runs through Dr. Mason's book—that modern science is the product of the combination of a craft and a philosophic tradition with regard to the study of Nature—and it seems that he regards the former as the more important. Thus, he says, the Michurin school of Soviet biologists, of whom Lysenko is the contemporary leader, arose from the work of a practical plant-breeder, while Mendelian genetics sprang from problems in the theory of biology and is largely an academic subject. This he regards as another example of the "difference in outlook between the craft and the scholarly traditions, which has existed throughout written history". The remark may be true, but scarcely in the sense that Dr. Mason intends. Nevertheless, his theme is an important one, for the instruments and experimentation of science have often depended on the resources of craftsmanship, and, more than this, the practical and pragmatic outlook of the craftsman has reinforced on occasion the analytical mind of the philosopher. Yet it is not enough to suppose that this is the whole of science, or that its history is solely concerned with tracing how the latter has successively given place to the former. It is therefore unfortunate that Dr. Mason has not given a fuller account of the way in which he supposes the 'craft' and 'philosophic' traditions to have interacted to yield science, which is so clearly distinct from either. At least in some instances this seems to lead to doubtful propositions, as when he remarks that "a barber-surgeon . . . might be a skilled sectionist and know intimately the anatomical structure of the human body". For while it may be convenient to his thesis to distinguish between this 'craftsman' and the academic Galenist, it is a mere supposition that the barber-surgeon was the better informed of the two.

It would be possible to point to a number of inaccuracies (John Ray's views on fossils are misrepresented on p. 319, perhaps because the author had not consulted Dr. O. E. Raven's authoritative study of Ray) which are inevitable in a work of this scope, even though it can no longer claim to be pioneering. One might ask more seriously: For whom is this book intended? It is not a monograph for the professional historian, nor is it really suitable for the general reader. If it is intended for the cultural education of scientists, it is open to the charge of taking a narrow, and perhaps not very subtle, view of the origins of their studies. May one mildly express the hope that the time has now arrived when it is no longer necessary for every historian of science to take the whole of it for his province?

A. R. HALL

Properties of Matter

By Dr. F. C. Champion and Dr. N. Davy. (Student's Physics, Vol. 3.) Second edition. Pp. xiv+328. (London and Glasgow: Blackie and Son, Ltd., 1952.) 27s. 6d. net.

FOR schools of physics which teach properties of matter at third-year honours level, this work should make an admirable text-book. It covers the usual subjects, such as gravitation, elasticity, surface tension, osmotic pressure and viscosity, and, in addition, it has chapters on the compressibility of liquids and solids and on seismic waves, which give the student a clear idea of the practical importance of general principles. The various subjects are treated extremely competently, and the physical approach is not subjugated to the mathematical, as so often happens with advanced text-books.

To the reviewer, the only jarring note occurs on the last page of the book, in a chapter on errors of measurement; this chapter discusses the various theoretical considerations involved in assessing the probable error of a quantitative result, and illustrates them by the steps involved in the determination of ϵ and h . The result given for ϵ in 1932 is $(4.7787 \pm 0.0052) \times 10^{-10}$ e.s.u. The authors then state, without comment, that the value computed in 1941 was $(4.8025 \pm 0.0011) \times 10^{-10}$ e.s.u. Is this not likely to produce in the student a sense of scepticism about the whole of the theory of errors? Surely the authors should have taken the opportunity of stressing the importance of applying the theory only when systematic errors have been eliminated.

Mass Spectroscopy In Physics Research

Proceedings of the NBS Semioctennial Symposium on Mass Spectroscopy in Physics Research, held at the NBS on September 6, 7 and 8, 1951. (United States Department of Commerce: National Bureau of Standards, Circular 522.) Pp. vi+273. (Washington, D.C.: Government Printing Office, 1953.) 1.75 dollars.

THIS book is a record of the proceedings of a symposium on "Mass Spectroscopy in Physics Research", sponsored by the National Bureau of Standards and held in Washington, D.C., during September 6-8, 1951. The thirty-five papers submitted at the conference together with the discussion ensuing from each paper are given in full, and the book ends with a comprehensive account of an informal discussion on experimental methods. A good knowledge of existing mass-spectroscopy techniques is essential in order properly to appreciate the papers.

An excellent opening paper by J. Mattauch summarizes the field of high-resolution mass spectroscopy with application to the measurement of absolute masses. This is followed by a number of shorter papers by some of the leading physicists in the field of mass measurement describing instruments, the results obtained and possible improvements to the existing equipments. A number of instruments using new techniques for mass measurement are described, for example, time of flight and cyclotron resonance. Isotope abundance measurements are briefly summarized, and techniques are described for some specific problems on the variations in the abundances of naturally occurring isotopes. Two large-scale mass spectrometers are described which have been used successfully for separating very small quantities

of pure isotopes for nuclear physics research. The last group of papers deals with a number of specialized subjects which serve to illustrate the wide field of application of mass spectroscopy in modern physics research. In the concluding section, on experimental methods, the use of the electron multiplier as a detector of positive ions is discussed together with the current ideas on high-vacuum gasket materials, ion-source plate spacers, etc. The omission of any papers on the analysis of solid materials by the mass spectrometer is a criticism of the conference rather than of the book.

The book is a valuable acquisition for any laboratory interested in the problem of mass measurement, and it indicates the extensive part played by mass spectroscopy in physics and chemistry research.

G. H. PALMER

New Pathways to Piano Technique

A Study of the Relations between Mind and Body with Special Reference to Piano Playing. By Luigi Bonpensiere. Pp. xxiii+128. (New York: Philosophical Library, Inc., 1953.) 4.75 dollars.

THIS book has been posthumously compiled from notebooks left by Mr. Luigi Bonpensiere. In it is developed a theory of 'ideo-kinetics' based on the author's private experiments. These purport to show that with proper training we can achieve far greater control over our bodily movements and much more rapid acquisition of complex skills than is possible by means of our usual methods of 'physio-kinetics'. In 'ideo-kinetics' the limbs to be used (for example, the hands in piano-playing) are completely disregarded and instead the person concentrates intensely on the image of the goal to be reached.

Mr. Bonpensiere was first trained as a technologist; but his claim to distinction lies in his contribution to art and musicology. Unencumbered by academic lore, he later turned his original mind to empirical problems of body-mind relations and carried out experiments which, if confirmed, may lead to remarkable conclusions. The material is unfortunately fragmentary and expressed in a strange terminology, but the reader willing to overcome these obstacles will find much in it which deserves close study. Although Mr. Bonpensiere illustrates the applications of his theory from piano-playing, the theory applies to every form of bodily skill.

Mr. Aldous Huxley contributes a vivacious and sympathetic preface, and his description of the author as "remarkably gifted" seems to be perfectly just.

JOHN COHEN

The Year's Work In Librarianship

Edited by W. A. Mumford. Vol. 15, 1948; pp. x+281. Vol. 16, 1949; pp. x+230. (London: Library Association, 1952.) 40s. each vol.; to members, 30s.

THE annual publication "The Year's Work in Librarianship" consists of a series of chapters by different authors, those dealing with national and university libraries, with special libraries, with library co-operation, with professional education and with subject bibliography containing most of the information of interest to the man of science as such. They are comprehensive and competent pieces of workmanship, factual rather than critical, but of more worth to the librarian than to his clients. The time-lag in publication seems excessive for a publication of this kind: Vol. 15, covering 1948, appeared in the spring of 1952, and Vol. 16, for 1949, at the end of 1952.

BRITISH COLONIAL RESEARCH

REPORT FOR 1952-53

RESEARCH undertaken by government agencies in the British Colonies is described in annual reports under the general title of "Colonial Research". That for 1952-53* follows the pattern of the past two years. It commences with the report of the Colonial Research Council, which this year is slightly longer, and to which is appended a list of schemes approved for research grants, April 1, 1952-March 31, 1952, and the report of the Director of the Colonial Products Advisory Bureau for 1951-52. Following this are the reports of the specialist councils and committees: the tenth annual report of the Colonial Products Research Council, the ninth annual report of the Colonial Social Science Research Council, the eighth annual reports of the Colonial Medical Research Committee and the Committee for Colonial Agriculture, Animal Health and Forestry Research, the sixth annual reports of the Colonial Insecticides, Fungicides and Herbicides Committee and the Colonial Economic Research Committee, and the reports for 1952-53 of the Tsetse Fly and Trypanosomiasis Committee, of the Colonial Fisheries Advisory Committee on Fisheries Research and of the Director of the Anti-Locust Research Centre.

The fifty-six new research schemes and fifty-four supplementary schemes made during the year, involving grants totalling £1,087,041, brought the net expenditure and commitment from Colonial Development and Welfare funds since 1940 to about £11 millions at March 31, 1953, while Colonial Governments or industry have provided a further £3 millions. Of the gross allocation, 32.8 per cent has been for agricultural, animal health and forestry schemes, 14.2 per cent for medical research, 12.9 per cent for fisheries research, 10.6 per cent for tsetse and trypanosomiasis research, 9 per cent for social science and economic research, 7.5 per cent for insecticides research, 5.1 per cent for research sponsored by the Colonial Products Research Council and 3.4 per cent for anti-locust research. Under the assistance provided by the United States Mutual Security Agency, Prof. J. C. Matthysse, of Cornell University, completed his investigation in Northern Rhodesia into the control of the tick vectors of protozoal diseases affecting livestock in Africa, and Prof. M. Stelly, University of Georgia, is undertaking in Kenya an investigation into problems of soil fertility, while two United States scientists are to investigate in West and Central Africa pasture production and management and the nutritive qualities of species of grass and other local feeding stuffs.

During October 23, 1952-March 20, 1953, Mr. G. A. Atkinson, who is now housing adviser to the Colonial Office, as well as Colonial liaison officer, Building Research Station, made an extensive tour of East Africa, India and Malaya, as well as visiting Mauritius and attending an African regional housing research conference in Pretoria, organized by the Commission for Technical Co-operation in Africa

South of the Sahara. The discussions at this conference indicated that plans for the extension of building research in British West Africa, French African territories and the Belgian Congo are under way, and problems on which further co-operation is desirable were specified: these include the documentation of existing standards of housing, studies of the design of dwellings in relation to climate, a general study of rural housing problems, and studies on sanitation, and on building in earth and earth admixtures. Interest in the use in the tropics of prefabricated systems of house construction, exported from the United Kingdom, has been stimulated by a display of designs at the Housing Centre, London, and, afterwards, by the exhibition of demonstration houses at the British Industries Fair, 1953, while earlier investigations of the Building Research Station for the Uganda Government on raw materials for cement manufacture promise to initiate a series of industries in Uganda which may transform the economy of the Protectorate.

Recruitment of field-staff for geodetic and topographic surveys failed to keep pace with resignations or transfers; but prospects for recruitment of field-surveyors and other technical staff are now much better and an increase of more than fifty in the total staff during 1953-54 is anticipated. The priority area for photo control has been the Volta River area, where a survey by a party of six Directorate surveyors and an average of twelve Gold Coast African surveyors is approaching completion. A party which has completed control in the Western Concession in Northern Rhodesia is proceeding to control mapping for the Kafue Gorge hydroelectric scheme. Changing priorities and the impact of National Service on the cartographic staff have adversely affected map production. With the appointment of seventeen additional geologists and chemists, the overseas scientific staff of the Colonial Geological Surveys numbered 180 on December 31, 1952, and each year shows an increase in effectiveness as the young officers appointed during the past five years grow in experience and confidence. In Northern Rhodesia a new carbonatite occurrence was being examined, and detailed geological mapping was in progress in parts of the Mumbwa district, where copper-gold mineralization is known. In Nigeria several million tons of easily worked coal have been located near the colliery at Enugu, and much geological work has been carried on in other coal areas. Geological mapping has been resumed in some States of the Federation of Malaya, while interest in the mineral deposits of Jamaica has been aroused by the investigations of its Geological Survey Department. Appreciation is again expressed of the practical interest of British universities in the geology and mineral resources of the Colonial territories.

In Singapore some investigations by means of electro-osmosis have been made into the drainage of Singapore Harbour; in addition, the cathodic protection of mild-steel harbour craft by the use of zinc and aluminium anodes, and the use of the North Dakota cone penetrometer in evaluating the stability of road beds and determining economical thickness of road material for a given density of traffic have also been subjects of study. The general shortage of

* Colonial Office. Colonial Research 1952-1953. Reports of the Colonial Research Council, Colonial Products Research Council, Colonial Social Science Research Council, Colonial Medical Research Committee, Committee for Colonial Agriculture, Animal Health and Forestry Research, Colonial Insecticides Committee, Colonial Economic Research Committee, Tsetse Fly and Trypanosomiasis Research Committee, Colonial Fisheries Advisory Committee, Director, Anti-Locust Research Centre. Pp. 268. (Cmd. 8971.) (London: H.M.S.O., 1953.) 7s. 6d. net.

qualified meteorologists has hindered the filling of staff vacancies, particularly in West Africa and the British Caribbean area, but the Hong Kong Royal Observatory has published papers on the upper flow structure near typhoons and the general circulation of the atmosphere over South-East Asia and the Western Pacific and an analysis of forecasting of the summer weather of the region, besides continuing investigations into the effect of strong winds on rain-gauge accuracy and ionosphere-weather relationship. Seven bases of the Falkland Islands Dependencees Survey were manned throughout the year, while at Signey Island in the South Orkneys the reproductive cycle of the Weddell seal was studied.

All the work of the National Institute of Oceanography, except the care and superintendence of the Discovery Collections, is now centred in its new building at Witley, near Godalming. A main object of its laboratory work is to improve our understanding of marine physics and of the environmental conditions and biological factors which determine the concentrations and fluctuations observed in oceanic fisheries. The marine physiologists have concentrated on the problems of sea-air energy exchange and its relation to the large- and small-scale water movements, while much of the effort in marine biology bears on the problems of the life-history, distribution and migration of whales. Studies of the factors which make some parts of the deep ocean more productive than others have centred around recent and earlier surveys of the regions influenced by the Benguela and Peru currents. Work on Colonial problems at the Road Research Laboratory has been limited by shortage of staff; but a report has been issued on the stabilization of a black cotton soil from Southern Rhodesia with lime and wood tar, and recommendations have been made for the use in concrete of four sands and aggregates from North Borneo.

The Colonial Products Advisory Bureau completed seventy-seven laboratory investigations and dealt with 763 inquiries. The more important of these mentioned in the Director's report for 1952-53 are: the collaborative investigations on the biological activity of extracts and the storage performance of flowers of three strains of Kenya pyrethrum, which have indicated that one strain having a high pyrethrin content loses about 25 per cent of its original active content during three months of storage; the preliminary examination of essential oils obtained by steam distillation of sage leaves collected from thirteen localities in Cyprus during April and June-September 1951; the examination of samples of *Cinnamomum parthenocaryon* oil from Sarawak as a source of safrole, required for the synthesis of piperonyl butoxide; the examination as paper-making materials of timbers from twenty-eight species of trees, from Kenya, Malaya and the Gold Coast; and the trials in the Sudan on the drying of goat and sheepskins, which have shown that suspension drying in the sun, without salting, is more satisfactory than dry-salting, subject to a limiting temperature. Further examination of jute and possible jute substitutes has confirmed that, for the finer counts of yarn, jute is in a class on its own, but with further experience it is probable that retting could be carried out satisfactorily in Colonial countries. The work on the identification of fibres has already proved its value, and continued attention was given to a survey of Colonial materials which might be developed as sources of tannin. Work

on groundnuts was extended and advice given on breeding and analytical problems of the oil palm.

The tenth annual report of the Colonial Products Research Council records the completion of the clinical trials of the fungistatic antibiotic, comirin, whereby application of comirin was effective in twelve cases of otomycosis in which the isolated organisms were an *Aspergillus* species or the yeast *Candida parapsilosis*, and promising results were also obtained in the treatment of various forms of tinea. Most of the cultures added during the year to the Hankey Culture Collection (which now comprises 547 strains) were dermatophytes isolated in the work on comirin. Prof. C. H. Hassall and his collaborators have improved the methods of isolating and purifying the antibiotic monomyoin, and progress is also reported in the separation and characterization of the active materials in the monomyoin complex. In the Sugar Technological Laboratory at the Imperial College of Agriculture, Trinidad, pilot-plant trials have indicated that superstats had no significant effect on scale formation. Methods for the production of sugar-cane wax were improved, and the hard waxes obtained by the new process from filter-press muds should compete with carnauba in the preparation of high-grade polishes. Results obtained in the production of lactic acid and its esters from molasses were sufficiently promising to justify installation of a pilot plant, and a 10 per cent yield of itaconic acid has been obtained on the sugar by culture of an *Aspergillus*, using the techniques adopted in penicillin manufacture.

The technique for the bulk preparation of the crude *Striga* germination factor has been improved and the method of testing stimulatory solutions modified. In work on carbohydrates, Prof. M. Stacey and his collaborators at the University of Birmingham have confirmed by chemical methods that the polysaccharide produced by the enzyme derived from *Acetobacter caprolatum* is a true dextran and have determined the structure of the dextran produced by a strain of *Betaoococcus arabinosacensis*; in addition, they have initiated fundamental studies on the enzymes responsible for the synthesis of the main chains of α -1:6-linked glucopyranose units and the branch points involving the α -1:3 linkages. Prof. A. C. Frazer and his colleagues at the University of Birmingham have shown that histamine release by dextrans is dependent upon concentration and size; and in Prof. S. Peat's laboratory in the University College of North Wales, Bangor, further evidence was obtained of the unbranched character of the maltosaccharides from amylose by their reduction to the corresponding alcohols with sodium borohydride; and from this reduction technique a new micro-method was developed for determining the molecular weights of maltosaccharides. Partial hydrolysis of the 'insoluble' laminarin of *L. cloustoni* yielded the three disaccharides, laminaribiose, gentiobiose and β -trehalose, and five trisaccharides, containing permutations of the β : β -, β :3- and β :6-links to be expected from the nature of the disaccharides.

The component glycerides of coconut and palm-kernel oils have been shown to consist of complex mixtures of mixed glycerides. Conophor oil, from *Tetracarpidium conophorum*, gave highly satisfactory results in technical trials, and Prof. H. D. Kay found that the cake remaining after the oil extraction was palatable to most cows and may form a good protein concentrate.

The ninth annual report of the Colonial Social Science Research Council records little change in the

recruitment position: difficulties in obtaining senior staff and for demography and legal sociology continued. No Colonial research fellowships in the social sciences were awarded during the year; but the Council has set aside £10,000 for junior fellowships, attached to Colonial universities and university colleges during 1953-56, and the Goldsmiths' Company is awarding two scholarships tenable at African university colleges in 1953. The five American social anthropologists appointed under the special scheme for training American scientists at British universities have now all returned from the field, and Dr. E. W. Winter's report on the Basamba is in its final stages. The first of a series of official visits to the regional institutes of social and economic research to consider probable requirements after March 31, 1956, was made to the West Indies Institute of Social and Economic Research at the end of March 1953. Detailed reports of the work of the regional institutes are appended to the Council's report. A Social Research Unit has been set up by the University of Malaya and was to start work in 1953. The report includes a survey of research in the Colonial territories financed independently of Colonial Development and Welfare Funds and notes particularly the work of the East African Statistical Department on the best methods of estimating population growth in under-developed territories; the inquiry into the political institutions of the districts in Tanganyika; and the inquiry of the Education Department of Northern Rhodesia into relative standards of children born in North Rhodesia and elsewhere, the effect of a different mother tongue, of health, occupation of parents, etc., on education and progress of European scholars. The Education Department of the University of Malaya completed its word-frequency count of written Malay.

Seven sections of the Ethnographic Survey of Africa were published during 1952-53, and eight other sections were in the press. Part 2 of the General Survey in the "Handbook of African Languages"—"The Languages of West Africa"—was published, and Part 3, "The Languages of East Africa", was being prepared for the press. Mr. Arnold Epstein's report on his legal studies in North Rhodesia was published under the title "The Administration of Justice and the Urban African". Work is well advanced on the programme of anthropological studies in Sarawak, and the West Indian volume of the Demographic Survey of the British Colonial Empire was expected to be published. A list of publications during the year by workers assisted from Colonial Development and Welfare Funds is appended to the Council's report.

Of the twenty-one research schemes under the scientific supervision of the Colonial Medical Research Committee at the beginning of the year, that for the study of malaria in North Borneo and Sarawak has been concluded, and that for the study of leprosy in Malaya is in abeyance. The Committee's eighth annual report records the filling of five vacancies, and the facilities of the overseas research units have been much used by specialist workers from the United Kingdom for the short-term study of specific problems. In West Africa steps are being taken to transform the Standing Advisory Committee into an appropriately enlarged West African Council for Medical Research, which will have under its supervision the Virus Research Institute at Yaba (to be renamed the West African Council for Medical Research Laboratories), the Hot Climate Physiology

Research Unit at Oshodi, the Leprosy Research Unit at Uruakoli, and the Loiasis Research Unit at Kumba, and will develop further research on malaria, yaws and tuberculosis. The East African Medical Survey, now a compact and active group, with ample housing and laboratory facilities, has been concerned essentially with fact-finding in the field of public health. Continued work at Kumba in the Cameroons on the breeding of larvae, and on the flies of the forest canopy, brought to light two new species of *Chrysops*, three species not previously known in West Africa, and three previously known only as the prey of wasps in the Congo. *Culicoides austeni* has been shown to be a vector of *A. persians* in the area, and surveys of infections with *Loa loa* and *A. persians* in the human populations in the rain forests, the forest fringe and the mountain grasslands of the British Cameroons have shown that both parasites reach an equilibrium of high incidence and intensity in small villages in the rain forest, the incidence and intensity falling very rapidly in the areas of derived savanna and forest relict, while neither infection is transmitted in the grassland. Investigation of the chemoprophylaxis and chemotherapy of filarial infections continued at the Liverpool School of Tropical Medicine.

A survey of the incidence and distribution of filariasis in the Southern Highlands of Tanganyika was made in September and October 1952, and additional investigations of filariasis are reported from the Institute for Medical Research, Malaya, where the risk of introducing the Pacific (non-periodic) variety of *Wuchereria bancrofti* through the arrival of Fijian troops has been lessened by screening contingents destined for Malaya and by treating microfilaria carriers with 'Hetrazan' before arrival: the Institute is co-operating in periodic examinations of the whole battalion. Malaria research in North Borneo, Sarawak and Brunei was terminated in 1952 after providing a method of eradication, by clearing scrub and admitting sunlight, which at the same time encourages the economic development of the land and the prosperity of the people. The work has also provided a basis for future malaria work in Borneo, and the observations suggest a method of control which may be applicable elsewhere in the East in jungle areas where *A. leucosphyrus* may be the vector. The work of the East African Malaria Unit was concerned mainly with the daytime distribution of the resting-sites of *A. gambiae* and *A. funestus* in houses and outside, and with the relation of the blood-meal to ovarian development. Studies in Trinidad on the effect of residual insecticide spraying in three mud-huts fitted with exit traps of the Muirhead-Thomson pattern indicated that an aqueous suspension of DDT was effective up to five months and 'Gammexane' only up to less than two months, although, when fresh, 'Gammexane' had a repellency effect to entrance. On the Gold Coast the human reservoir of malaria infection in villages in a hyperendemic area was investigated from headquarters in Accra. A full report on trials of chloroquine, amodiaquin and pyrimethamine in Malaya is in preparation, and further tests of residual insecticides in window-trap huts have also been made on Malayan mosquitoes.

The East African Virus Research Institute, Entebbe, Uganda, where expansion on the clinical side is desirable, has concentrated its field-work on yellow fever in the drier country, where bush-babies (*Galago* spp.) and not monkeys appear to be the main

animal hosts of the virus. Some survey work on the Rift Valley fever virus was carried out and a strain of the Coxsackie virus was isolated from a member of the Institute's staff. In the work of the Scrub-Typhus Research Unit based on the Institute for Medical Research, Malaya, the emphasis was shifting to other infections which involve animal reservoirs, and the revised objective of the Unit is a continued study of animal ecology with special reference to medical problems. The work of the United States Army Medical Research Unit (Malaya), of which a summary is again given, has included studies of the resistance to penicillin and carbomycin of staphylococci from North Borneo, Malaya and the United States; investigations on Trombiculid mites were to be resumed in 1953. Surveys were made of relapsing fever in the Usambara Mountains, Tanganyika, and in the Teita Hills and Kwale district in Kenya. At the Lister Institute of Preventive Medicine a special study was made of the sera of the African species of the family Bovidae, and a completely new technique for identifying blood-meals of closely related species was being investigated, while the studies continued of serum proteins, of nitrogen balance and water content, and of hematology.

The Hot Climate Physiology Research Unit at Oshodi, Nigeria, completed a survey of the energy cost of most of the everyday tasks of the farmer, and started one of purely industrial tasks, particularly the energy cost of head-carrying. At the Uzuakoli Leprosy Settlement, Nigeria, pharmaceutical and therapeutic studies of sulphones have confirmed that small oral doses of 'Dapsone' are an effective, simple, safe and widely practicable form of chemotherapy of leprosy, and the good results previously recorded with *p*-acetamidobenzaldehyde thiosemicarbazone have been confirmed. In Nigeria the findings of the previous goitre survey were confirmed; the areas of obvious goitre lie on granite or are associated with granite outcrops in marine sediments or with drainage areas off granites, and such areas have been mapped in consultation with the Nigerian Geological Survey. The Field Research Station, Fajara, Gambia, continued its investigations into nutritional disorders, including the study of methods of determining the amino-acid content of tropical foods, and the scope of the work was extended to include studies on filariasis and schistosomiasis (particularly the treatment of elephantiasis of the leg) and the mosquitoes which may transmit *W. bancrofti* in the Gambia. Some notes are included on the medical work undertaken and financed by the Medical Departments of Colonial Territories—for example, the treatment of malaria with daraprim in Kenya, clinical trials of 'Sulphetrone', 'Dapsone', 'Thioacetazone', 'Ethionine', 'Isoniazid' and 2-anilino-3-amino-5-phenylphenazide hydrochloride at the Leprosy Hospital, Makogai, Fiji, and a study of 'vomiting sickness' in Jamaica.

Grants totalling £372,286 were made during the year for new and existing schemes from Colonial Development and Welfare Funds by the Committee for Colonial Agricultural, Animal Health and Forestry Research, the annual report of which again acknowledges particularly the assistance of the Commonwealth Institutes of Entomology and of Biological Control and of the Commonwealth Mycological Institute. Progress in some sections of the East African Agriculture and Forestry Research Organization was retarded by the declaration of a State of Emergency in Kenya, but research in soil micro-

biology was started and a satisfactory technique for inoculation of maize for resistance to the American rust disease caused by *Puccinia polysora* Underw. was taking shape as a result of co-operative work with Amani as well as the Kenya and Uganda Departments. Co-operative work with the Cotton Research Station, Namulonge, has demonstrated the repellent effect of certain insecticides against the *Lygus* pest. Soil surveys at different category-levels were continued as well as laboratory work on the fertility of tropical soils. The major buildings and other facilities of the new headquarters of the East African Veterinary Research Organization at Muguga South were completed or well advanced by the end of the year under review, and earlier findings have been confirmed that treatment of bovine trypanosomiasis with 'Antrycide', while effective in the early stages, is much less so in advanced trypanosomiasis, and that prophylactic treatment of cattle in contact with tsetse fly should be given at least once every two months. The main factor determining the success of the drug in protecting cattle appears to be the severity of the challenge by trypanosomes, which in turn depends on the nature and number of the tsetse flies to which the cattle are exposed. Research was continued on the systematics and life-cycles of the paramphistomes of domestic ruminants.

At the West African Cacao Research Institute demonstration of the control of swollen shoot by regular inspection and cutting-out of symptom-bearing trees and replanting was continued, as well as investigations on the symptoms and classification of cacao virus strains from the Gold Coast, Nigeria and the Ivory Coast, and on the mealybug vectors of these strains; and the search went on at the West African Rice Research Station, Rokupr, Sierra Leone, for maize varieties which combine high yield and resistance to attack from the rust disease pathogen *Puccinia polysora*. At the British West Indies Central Sugar-Cane Breeding Station, Barbados, further progress was made in the pure-line breeding programme, and a satisfactory cytological technique, involving pre-treatment of root-tips in α -bromonaphthalene solution to condense and spread metaphase chromosomes, was evolved. Investigations at the Imperial College of Tropical Agriculture, Trinidad, strengthen the opinion that the deterioration of cacao soils is due to loss of litter, crumb, and highly organic topsoil through erosion, wastage by oxidation of organic matter and nutrient exhaustion. The ecological land-use survey of British Honduras commenced in August, and the preliminary ground survey of the Northern, Corozal District was virtually complete by the end of the year under review. Among researches undertaken by the Colonial departments may be mentioned one in Barbados on the control of cane-root-destroying pests, such as *Diaprepes abbreviatus*, *Olethreus ornithi*, and *Aceropyga* ants and wood ants in cane fields with the gamma isomer of benzene hexachloride diluted with milled coral limestone; in the Gold Coast on the control of maize-stem borers with DDT and benzene hexachloride preparations; on the improvement of biological control of coffee-mealybug (*Planococcus kenyae*) in Kenya by introducing and establishing further species of natural enemies from Uganda; studies on the control of black pod disease of cocoa (caused by *Phytophthora palmivora*) in Nigeria; the studies of control of tick-infestation of cattle in Northern Rhodesia, which indicate the wide field of application in Africa for the portable power-spray; and of the *Theraptus*

damage to coconuts in Zanzibar, where an experimental double aerial spraying with DDT in oil formulation was given to five hundred acres of coconut plantation.

The sixth annual report of the Colonial Insecticides, Fungicides and Herbicides Committee includes an account of the work of the Colonial Insecticide Research Unit at Porton, where studies continued on the sorption of insecticides by certain types of dried mud used for native houses in many parts of the tropics in an attempt to explain the relatively poor effect of DDT against certain species of mosquito (notably *Anopheles gambiae*), and a preliminary wind tunnel study was made of the deposition of small particles on various obstacles, including tsetse flies, at low wind speeds. Air-borne drops appeared to be deposited more readily on tsetse flies at rest on the obstacles than on the obstacles themselves, and for such deposition the optimum drop-size range with the cylinders and disks used at wind speeds of up to 4 m.p.h. is 10-30 μ , although since drops in this size-range are not collected efficiently by the cylinders and disks, larger drops are required for deposition on them. A team from the Unit continued the aircraft-spraying trials against tsetse flies in field experiments at Urambo in the western Tanganyika *morsitans* belt and at Maruzi in Uganda in thicket typical of much tsetse brush in East Africa, and very promising results were obtained by aircraft spraying five hundred acres of coconuts infested with a coreid bug (*Therapsus* sp.) at Zanzibar using a 9.2 per cent solution of DDT in oil as well as in spraying with a DDT emulsion five hundred acres of beans near Arusha, which were heavily infested with larvae of the American bollworm (*Heliothis armigera*).

The malaria eradication experiment in Mauritius was terminated: malaria transmission virtually ceased with the elimination of *A. fuscus*, and the reduction in houses of *A. gambiae*. A full report was in preparation of the experiment in malaria control in Malaya, now terminated, in which promising results were obtained with both DDT and benzene hexachloride. Very promising results were obtained in defoliation experiments with bush infested with *G. palpalis* and *G. pallidipes* in Kavirondo, Kenya; but in the experiments with the *n*-butyl esters of 4-chloro-2-methylphenoxyacetic acid, 2:4-dichlorophenoxyacetic acid and 2:4:5-trichlorophenoxyacetic acid, overall spraying of regenerating savanna-thorn bush at Shinyanga, East Africa, and regenerating *Isobertinus* woodland at Kikare when the regenerating shoots were 2-4 years old over a two-year period failed to eradicate the bulk of the species.

At the Imperial College Field Station, Silwood Park, transport of DDT solutions in lanoline across the integument of blowflies was investigated and studies of the contamination of flies exposed to particulate deposits continued. At Rothamsted Experimental Station the rate of loss of insecticidal effect of DDT deposits on living foliage in the glass-house was studied under various conditions. In Uganda investigations on the control of blackarm disease of cotton were completed, while in Malaya control of insect pests troublesome in the field establishment of young cacao were controlled by soil treatment with benzene hexachloride and dusting the plant with DDT wettable powder.

The Colonial Economic Research Committee still finds it difficult to recruit qualified candidates, but the decision to invite universities and university

colleges to propose schemes for economic research has had good results. The Committee's sixth annual report records that Dr. J. Greaves's monograph on "Colonial Monetary Systems" was in the press, as was Dr. A. R. Prest and Mr. I. G. Stewart's report on "Nigerian National Income, 1950-51". The Committee has approved three grants: for Dr. F. C. Wright's study of the structure and organization of the distribution in Tanganyika and Nyasaland; towards half the recurrent expenditure of an Economic Research Unit at the University College of the Gold Coast until March 31, 1956; and for a scheme to promote the study at the University College of the West Indies of the methodology of capital formation, with special reference to capital investment in Jamaica.

The report of the Tsetse Fly and Trypanosomiasis Committee for 1952-53 records further advances in the integration of tsetse research and of research on human and animal trypanosomiasis in East Africa. Satisfactory results have been obtained in experimental reclamation projects, and pilot schemes of practical reclamation in conjunction with the utilization of land have been started in the three mainland territories. The Antryoids Research Scheme was terminated at the end of March 1952, but investigations were being continued under the Trypanosomiasis Research Laboratory. The West African Institute for Trypanosomiasis Research also reports satisfactory progress. Reports on the use of 'Antryoids' methyl sulphate for curative purposes continued to be generally favourable. Special attention was given to the study of *T. vivax*, including work on its transmission by *G. palpalis*.

The annual report on Fisheries Research of the Colonial Fisheries Advisory Committee records that the number of fishery officers was stabilized at about fifty-four, and recruitment and training were largely concerned with replacements. Commitments for new schemes and for the extension of existing ones until March 31, 1956, are estimated at £85,510, with an uncommitted balance of £68,800. At the Inter-territorial Fisheries Research Station at Jinja a new technique to determine chemical deficiencies in lake waters has been developed, using algal cultures as indicators, and results have shown that sulphates may sometimes be the primary deficiency. Considerable advances have been made in studies on the taxonomy of the fishes *Haplochromis* and *Tilapia*. At the Inter-territorial Marine Fisheries Research Station at Zanzibar the emphasis has been on the distribution of the big surface fishes, while continued experiments at the West African Fisheries Research Institute on the control of marine wood-borers by concussion have shown that, while detonation by small explosive charges greatly decreases the incidence of the common shipworm *Teredo*, it is ineffective against the *Martesia* wood-borer. No progress is reported at the Research Station for Fish Culture in Malaya.

The report on Locust Research and Control, 1952-53, covers the work of the Anti-Locust Research Centre, which received 1,265 reports on the locust situation from forty-one countries and territories. Besides its studies of factors affecting the rate of sexual maturation in the desert locust, it carried out with the Desert Locust Survey investigations, on the Somali peninsula, on swarms of desert locusts during August-November 1952, which threw some light on the mechanism of displacements associated with the Inter-Tropical Convergence Zone. During the year

the desert locust situation, in contrast to that in the outbreak areas of the African migratory and the red locust, was extremely serious, particularly on the Somali peninsula and in Arabia. In the Somali Peninsula and the coastal areas of Saudi Arabia it was brought under control by the Desert Locust Control Organization of the East Africa High Commission, in co-operation with the Saudi Arabian and Ethiopian authorities and the Somali Administration.

LIMITS TO A FIRM'S CONTROL OF LABOUR TURNOVER

By DR. HILDE BEHREND

Faculty of Commerce and Social Science, University of
Birmingham

LIKE all social and economic phenomena, labour turnover is determined by the interaction of numerous factors involving both economic and non-economic motives. While all these factors operate simultaneously, some of them exert a much stronger influence on the level of turnover than others. The ability of a firm to limit its labour wastage will depend on the strength of the influence on turnover of factors which it can control or modify; it cannot hope to alter a high turnover-rate if it is due to external factors, outside its control.

Opinions differ about the weight which must be attached to external and internal factors as determinants of labour turnover. Some writers, such as Florence¹, Long² and James³, emphasize the importance of external factors while acknowledging that the firm has a part to play. Other writers, for example, Cook⁴ and Greystoke⁵, stress the significance of the individual firm. The Tavistock Institute team, Rice, Hill and Trist⁶, take up an extreme position and assert that labour turnover is a "function of an industrial organisation as a social institution", and this view, which is not backed by valid evidence, appears to have gained considerable ground in recent years. (For an examination of the validity of evidence, compare Behrend⁷.) My own research points to a different hypothesis.

The problem is one of finding objective criteria to assess the relative influence of external and internal factors on labour turnover. In developing a technique the following considerations are of importance. While labour turnover must be regarded as a function of both external and internal factors, it is conceivable that the difference between two labour turnover-rates can be traced back to only one group of these variables. As external factors operate in the whole community, their influence, if it exists, must be noticeable in many firms and not restricted to one firm. Therefore, if we discover evidence that there exist certain types of differences in turnover which are found in the majority of factories, external factors can be assumed to be at work. On the other hand, the effect of internal factors must be restricted to one particular plant. Thus, if we find an isolated instance of an observed significant difference in turnover, internal factors can be assumed to be at work.

The extent of the incidence of differential turnover-rates or of changes in labour turnover thus provides

a criterion for assessing the influence of external as opposed to internal factors on labour turnover.

This criterion can be applied to the findings of labour turnover research which has revealed that the following five types of differences in labour turnover at the same point of time exist among workers in manufacturing plants (cf. refs. 1-5 and others).

(1) Labour turnover differs for the sexes. In practically all factories in England it is higher for women than for men in the same age and length of service group. It must be stressed, however, that this is linked with type of work (cf. ref. 4).

(2) Labour turnover varies for different age-groups. It tends to decrease with age, at least after the age of thirty, and this fall appears to be fairly universal.

(3) Labour turnover differs for workers with different lengths of service. It is well known that in all factories turnover is highest among newcomers and lowest among long-service workers.

(4) Labour turnover differs with type of work. It tends, for example, to be lower for skilled workers than for unskilled ones. Contrary to expectation, there appears to be no evidence that these variations are linked to differentials in wage-rates or earnings.

(5) Labour turnover varies with the number of jobs in the local labour market. In a large town with many factories wastage-rates tend to be higher than in an isolated area where one factory is the main employer.

Labour turnover thus differs with sex, age, length of service, occupation and employment opportunities. These five types of variations have been found to be general phenomena, observable in the majority of factories, and must thus be attributed to the operation of general external factors.

It follows from these findings that comparisons of the level of turnover of different factories and departments at the same point of time, with the view of isolating the effect of the firm on labour turnover, should be based on standardized rates, namely, on age-specific turnover-rates for men and for women in given occupations belonging to specific length-of-service categories and living in similar labour markets. So far as I know, the construction of such rates for inter-factory comparisons has never been attempted.

Fortunately, standardization of turnover-rates is mainly essential when comparing different factories or departments at the same point of time; it does not appear so necessary when one is comparing figures for the same factories or departments for successive periods of time provided they have fairly stable population structures. (The comparison would be based on the simplifying assumption that the characteristics of the population do not change significantly from one year of observation to the next and must be restricted to factories with stable population numbers.)

When studying successive periods of time, external factors can be deemed to be at work if certain changes in labour turnover occur in the majority of factories, while internal factors can be assumed to be operating if the observed change is an isolated event restricted to one firm, factory or department, not experienced by a control group of factories, or deviating from the trend of the control group.

A considerable amount of evidence is available to show that changes in external factors lead to widespread and marked changes in the level of labour turnover. Data published by Florence¹, Long², Woytinsky⁸ and myself⁷ show that changes in the level of turnover correspond to changes in the level

of employment. Under full employment labour turnover tends to be high, and it falls with rising unemployment. As small an increase in the unemployment-rate as a rise of 0.4 percentage points was found to have led to a very marked reduction in the level of labour turnover².

The course of the Second World War can also be shown to have affected the level of labour turnover³.

What is the effect of changes in internal factors? Firms claim that introduction of the incentives and bonus schemes, of personnel management, of induction and training schemes, and of better management and supervision will each lead to a fall in labour turnover. Yet it is extremely difficult to find valid evidence to prove this. Most of the claims of success are not substantiated by data for control groups. In published literature and in data collected by myself, I have been unable to discover more than four cases of the effective reduction of labour turnover in experimental plants, where the control groups showed no corresponding change.

Florence⁴ quotes a study made by the U.S. Department of Labour in 1920 which shows that the introduction of "definite labour policies and centralized employment machinery" in a number of 'experimental' establishments was followed by a reduction in the wastage-rate from well above that of the control group to less than half that of the control group. Long⁵ gives an example where a change in the management and organization of a factory together with the introduction of time and motion study led to a proportionately greater fall in the male labour turnover-rate of the experimental plant than the ordinary post-war reduction shown by two other factories owned by the same firm. In a department of Company J, I found that a change in supervision together with a complete re-organization of the department, including the introduction of time and motion study, was followed by a remarkable drop in labour turnover, while the other departments of Company J showed no corresponding change. In Company P, labour turnover was reduced significantly from one year to the next, while other factories in the same area showed no comparable reduction. This was attributed to the combined effect of "important changes in management attitude, in pay, in conditions, in benefit plans, in the efficiency of supervision, and in other aspects".

It can be seen that these four cases all entailed a series of simultaneous and extensive changes in organization. But if really radical changes in organization take place, they probably involve changes in factors which were shown earlier to be external factors, for example, in type of work. This would be true of three of the four cases. Furthermore, such changes would normally be followed by changes in the work-force, for better work methods mean more output, and population numbers are adjusted to the output target. Other external factors such as the composition of the work force and employment opportunities are thus likely to alter.

On the whole it appears to me that all the available evidence suggests that quite small changes in external factors, namely, in the level of employment, produce far more pronounced changes in the level of labour turnover than small changes in internal factors. Only extremely radical changes in internal factors can achieve similar results; but if such extensive changes take place, they probably involve changes in external factors.

One can go one step further and say that external factors, particularly the level of employment, are the decisive factors in this field which determine not only the behaviour of individuals but also the action of firms. When the level of employment changes, the labour problems of a firm alter and this affects management's policy with regard to all aspects of labour management. Changes in external factors thus give rise to changes in internal factors. Internal factors are not independent variables, but are largely an adjustment to general factors as they affect the firm or an attempt to modify them. Under full employment, for example, the firm's response to the shortage of labour is to 'woo' workers to stay with it by the introduction of elaborate employee services of all kinds. Theoretically it would appear highly plausible that these measures are effective and reduce the high level of labour turnover. In practice, however, there is very little evidence to support the claim that labour turnover can be modified by organizational action—short of changes in the whole set-up. This appears to be so even though we know when and where action is necessary. It is needed in times of full employment, and it must concentrate on modifying the influence of age, length of service and type of work, by trying to create a sense of loyalty and 'belonging' in the newcomer and in the young worker, and by studying the type of work to see whether irritating elements of the job can be eliminated and 'traction' increased. (Traction is 'the feeling of being pulled or drawn along by the inertia inherent in a particular activity'; compare Baldamus¹⁰.)

It may be objected that I have ignored the most important incentive the firm can offer, namely, wage-differentials, and that the payment of relatively higher wages than neighbouring plants is likely to be an effective tool of control at the disposal of the firm.

Labour turnover research, however, has provided no evidence so far to show that relatively higher wages stabilize a firm's work-force. This may be partly because the effect is difficult to isolate and partly because few firms pay high enough wage-differentials. A firm's ability to pay higher wages than its neighbours is limited by external factors, such as economic market forces which determine the receipts for its sales. Managers frequently express the belief that they cannot afford to pay higher wages because increased labour costs reduce profitability and they feel this more than offsets any gain in labour stability. They thus do not seem to consider the use of higher wages as a tool of labour control to be a workable proposition. (The introduction of wage-differentials which aim at paying relatively higher wages than other factories means that a firm pays a higher wage for a given output than previously. This must not be confused with the use of incentive payment schemes where increased pay is linked to increased output and therefore does not increase costs.)

It appears that the firm's control over labour turnover is very limited, and that labour turnover is mainly determined by factors outside the firm's control, modifiable only to a small degree. The problem so frequently discussed in economics of the different effectiveness of the 'stick' and the 'carrot' applies. Unemployment as the stick appears effective as a limiting factor to labour turnover, but we do not yet know how to make organizational policy act as an effective carrot, although firms have been

searching for such an incentive ever since the pressure from unemployment has been relaxed.

TOTAL SOLAR ECLIPSE OF JUNE 30, 1954

A TOTAL eclipse of the sun will occur on June 30, 1954, the belt of totality stretching from near Minneapolis, where eclipse comes at sunrise, through north-eastern Canada and Greenland, across the Faroes, Norway, Sweden, the Baltic and south Russia, finally ending at sunset not far from Peshawar. Many European astronomers are proposing to go to southern Sweden to make observations, since this is an easily accessible portion of the eclipse track and the chances of a clear sky are reasonably good (about 50 per cent). Mid-eclipse comes near noon in the Faroes and in the early afternoon in Scandinavia. The belt of totality is about ninety miles wide, and near the centre line the duration of totality is 2½ minutes. The corona may be expected to be of the type associated with minimum sunspot activity. Preparations are known to be under way for parties of observers from Great Britain, Eire, France, Switzerland, Holland, West and East Germany, Italy and Canada. Swedish astronomers, who are naturally taking a very active interest, are organizing groups of observers to work at three or more separate places.

The Royal Greenwich Observatory is to send a small group to measure the gravitational deflection of light by the sun. This is a fairly favourable eclipse for this purpose, as the star field is a good one, although the duration of totality is not specially long. Another group from Greenwich will be engaged in measuring accurate positions of the cusps for geodetic purposes. The Cambridge Observatories are planning several types of observation: (1) measurement of chromospheric line profiles with a large spectrograph giving a dispersion of about 1 Å/mm.; (2) measurement of the electron temperature of the chromosphere by Zanstra's method; (3) observation of the corona in the light of the green line 5303 Å., using an interference filter and a Fabry-Perot interferometer of low resolving power, to examine the distribution of line width, and of line of sight motion. This last experiment is being carried out in co-operation with the St. Andrews Observatory. St. Andrews is also sharing a project with the Potsdam Observatory, to measure the deflection of light by the sun with an elaborate apparatus developed from that used by Potsdam observers some twenty-five years ago in Sumatra. The University of London Observatory is to carry out photographic photometry of the corona, with a new arrangement which should reduce trouble from scattered light and also should extend the range of surface brightness measurable.

The Dumank Observatory is to measure line-widths in the spectrum of the low chromosphere, using a Fabry-Perot interferometer.

All the foregoing parties will observe in various places in south Sweden. In addition, the Cambridge Observatories, with the help of the R.A.F., are photographing the outer corona in polarized light from an aircraft at about 30,000 ft. altitude, using a multi-lens camera designed for freedom from scattered light. Observers from the University of Edinburgh are also utilizing aircraft, in an attempt to detect a daylight aurora during totality. Both these flights will probably take place north of the Shetlands.

The plans of astronomers from other countries are not yet generally known; but a few details can be given here. French observers (MM. Dollfus and Michard) will use a spectrograph devised by the late Dr. B. Lyot, permitting photography of the coronal spectrum simultaneously around almost the whole sun. Dutch astronomers (Prof. M. G. J. Minnaert and Dr. J. Houtgast) will examine the Fraunhofer spectrum of the corona, and the distribution with respect to height of material in the chromosphere. Two Canadian parties intend to observe the chromospheric spectrum, one from the Dominion Astrophysical Observatory, Victoria, B.C., with a slitless instrument, the other from the Dominion Observatory, Ottawa, with a high-dispersion slit spectrograph.

OBITUARY

Dr. Karl B. McEachron

DR. KARL B. MCEACHRON, consultant to the General Electric Company at Pittsfield, New York, died in hospital on January 24, aged sixty-four years.

Dr. McEachron's name will always be associated with high-voltage research work and with the study of lightning. He was an instructor for some years in the Ohio Northern University and at Purdue, and in 1922 took charge of the research and development section of the Lightning Arrester Engineering Department of the Pittsfield factory of the General Electric Company. Here he developed techniques for producing and recording electrical transients of very short duration, and was one of the first engineers to apply surges from an impulse generator directly to overhead transmission lines in order to study the attenuation of high travelling-wave voltages and their effect on terminal apparatus. He was largely responsible for the successful production of the "Thyrite" lightning arrester, embodying material composed of carborundum and graphite having a fourth-power voltage/current characteristic. His published work on this development is to be found in the *Transactions of the American Institute of Electrical Engineers* in the years 1928-33, and for this he received the Charles A. Coffin Award of the Edison Electric Institute in 1931 and the Longstreth Medal of the Franklin Institute in 1936.

In 1933 Dr. McEachron was appointed engineer-in-charge of the High Voltage Engineering Laboratory at Pittsfield and there began the study of lightning flashes striking transmission lines and—later—striking to the top of the Empire State Building, New York. He installed oscillographs on the top floor connected to the radio antenna system of the National Broadcasting Company twelve hundred and fifty feet above street-level and placed a variety of types of Boys's cameras on the fifty-sixth floor of

500 Fifth Avenue, from which a good view of the top of the Empire State Building was obtained. Schonland had by this time established the existence of the downward directed 'leader' stroke to the lightning flash, but McEachron's paper to the Franklin Institute in 1939 showed that in fact nearly all lightning flashes to the Empire State Building begin by discharges extending in step-by-step formation from the top of the building to cloud. The oscillograms of the same lightning strokes disclosed that although the luminosity often falls to zero between the successive strokes of a lightning flash, the current through the oscillograph did not. There were long 'continuing strokes' lasting many milliseconds between the high luminosity large current strokes. McEachron showed that these continuing currents in fact carried larger charges to ground than the

charge associated with the bright main strokes, and it was suggested that these 'continuing strokes' might be responsible for many strange failures of lightning arresters and may explain the cause of fires initiated by lightning. For his outstanding work in gaining quantitative data on lightning discharges McEachron was awarded the Edison Medal of the American Institute of Electrical Engineers, being the thirty-ninth holder of that Medal.

He was one of the most-sought-after speakers in the General Electric Company and lectured extensively in the United States and Canada. He accumulated an immense collection of photographs of lightning, and gave visitors from overseas a most cordial welcome and a fascinating review of lightning studies. He leaves a widow, three sons and two daughters.

T. E. ALLIBONE

NEWS and VIEWS

The Ancestry of Sir Isaac Newton

At an ordinary meeting of the Scottish Genealogy Society, held in Edinburgh on February 16, the honorary secretary of the Society, Rolland J. B. Munro, read a paper entitled "Notes on the Ancestry of Sir Isaac Newton", in which he claimed that there is a strong possibility of Newton being of Scottish descent. Newton occupied himself very much with genealogy, there being evidence of his interest in this in 1659, at the age of seventeen; and after 1705 he made a painstaking search to uncover his ancestry, leading to a great mass of papers sold at the Ridd Sale in three portions, the smallest portion of which was bound in seventeen volumes. Mr. Munro's main argument was that it was Newton himself who, as a result of these investigations, claimed Scottish ancestry. Sir Isaac's grandfather, Robert Newton, undoubtedly bought the manor of Woolthorpe, and Mr. Munro maintains that Robert had left Scotland with the court of King James VI of Scotland, afterwards to become James I of England. Sir Adam Newton, Bart., of Charlton in Kent, the son of an Edinburgh baxter and burgess, a scholar of high repute and favourite of Andrew Melville, was tutor and secretary to Henry, Prince of Wales, the elder son of James, who died early. Sir Adam also had a brother Robert, and it is suggested that he became Robert Newton of Woolthorpe and lord of that manor; for, if he were an Englishman, his ancestry seems to be enigmatic. The Charlton Newtons are clearly a cadet of the Newtons of that ilk in East Lothian, from whom, so Sir Isaac is said to have stated, his grandfather claimed kinship and descent. Evidence was shown by Mr. Munro that the Lairds of Long Newton in East Lothian had suffered by adherence to the cause of Mary Queen of Scots, that one of them went to England, and that for these financial and material hardships they were rewarded by James VI. Robert and James Newton followed with Sir Adam, but were not so lucky as the latter, and each, it may be significant, eventually went to the University of Padua, where Galileo had taught the doctrines to which Sir Isaac added his intellectual seal. Attention was also directed by Mr. Munro to the fact that one of Newton's relatives owned Gordon Mill, near Kelso, during Sir Isaac's life-time, and that this cousin lived with him for a period.

Continued Employment of Older People

REPLYING in an adjournment debate on the employment of older men and women in the House of Commons on February 5, the Parliamentary Secretary to the Ministry of Labour and National Service, Mr. H. Watkinson, pointed out that the National Advisory Committee on the Employment of Older Men and Women is a standing committee which has only just started its work. The research sub-committee also set up meets frequently, and other sub-committees will be established if necessary. Mr. Watkinson urged that the whole problem should be examined in the light of two principles: capacity, not age, should be the first consideration in recruiting staff or engaging people, and all who can continue to give effective service in their occupation should have the opportunity of continuing, if they wish, irrespective of age. Mr. Watkinson referred particularly to the shortage of skilled engineering craftsmen and to the value of older craftsmen as a reservoir of skill, who could at least be employed for shorter hours or as instructors. With regard to the professional man and the obstacle which pension schemes present to continued employment, he said that the Association of Superannuation and of Pension Funds had authorized him to state that the Association could show any employer who felt that a pension fund or superannuation fund is a bar to the employment of older men and women how to modify that policy. After referring to the efforts of the Ministry to influence opinion and to spread the knowledge of what the Advisory Committee is doing, Mr. Watkinson appealed for the co-operation of employers, trade unionists, members of Parliament and all people of goodwill in solving a problem which is of vital importance to the national economy and to the health and happiness of older people themselves.

Nationalized Industries and Accountability

In opening a debate in the House of Commons on February 8, on the Report of the Select Committee on the Nationalized Industries, the Lord Privy Seal, Mr. H. Crookshank, said that in principle the Government accepts the idea of a select committee and also the recommendations of the present report on that subject, subject to modifications and to consideration of the views expressed in Parliament. The Government would prefer to keep open the

possibility of a joint select committee of both Houses. While the Government agrees entirely that the terms of reference of the proposed committee should not enter into questions of detailed administration, it does not agree with the proposal that the committee should inquire into future plans and programmes as suggested in the report. To commence with, the Government thinks that the committee should not exceed ten to fourteen members, and that it would be a mistake to provide the committee with a permanent officer of the House, such as the Comptroller and Auditor General. It prefers the alternative suggestion of beginning with a clerk from the committee office and with someone of the nature of a Treasury liaison officer. If an independent officer is then found to be required, the matter could be considered by Parliament. Tentatively, Mr. Crookshank suggested that it would be much wiser not to publish all the evidence but merely reports from time to time, and it is not thought that every industry should come, in some form or other, before the select committee each year. It should be made clear that the constitution of the committee should not touch in any way the existing rights of ministers under legislation.

Auditing of Non-Recurrent Grants to British Universities

In a Special Report from the Committee of Public Accounts (Session 1953-54: Treasury Minute and Abstract of Appropriation Accounts, 67. London: H.M.S.O., 1954; 1s. net) the Treasury refers to the recommendation of the Committee, in its third report for session 1952-53, that the books and accounts of the universities of Great Britain relating to their expenditure of non-recurrent grants should be open to inspection by the Comptroller and Auditor General. The Treasury reiterates that it has no reason for thinking that the sums voted have not been wisely administered. The essence of the relations between the universities and the Government has been that the Treasury should avoid any detailed control of the activities of universities. Neither the Treasury nor the University Grants Committee has ever claimed the right to examine the universities' books, and the Treasury believes that to do so in the way suggested by the Committee would lead to increased intervention and extended control in a way which would prejudice the present harmonious relation between the universities and the University Grants Committee. The Treasury, however, foresees no difficulty in making satisfactory arrangements with the universities which would enable the Public Accounts Committee to satisfy itself that the grants are duly appropriated to meet the expenditure for which they are made, though the precise part to be played by the universities' auditors and professional advisers will require consideration. With regard to the more important question of ensuring economy in the expenditure of non-recurrent grants, the Treasury is considering whether the assurances desired could be obtained by some other means; thus the University Grants Committee might appoint one or more persons to report to it on any changes necessary to ensure that the methods adopted by the universities for contracting and recording and controlling expenditure are reasonably designed, and properly applied, to provide effective safeguards against waste, extravagance or other abuse. Such a report would be made available to the Public Accounts Committee with a note of any action taken or proposed. The

Treasury proposes to discuss this matter with the university authorities.

Co-ordination of Research In Scotland

In reply to a question to the Secretary of State for Scotland, on February 2, referring to co-ordination between government, industrial and university laboratories for pooling the results of their scientific and technological research work, Mr. J. Stuart stated there is free exchange of research information between the universities, industrial research associations and the Department of Scientific and Industrial Research. That Department operates a technical information service available to large and small firms alike, and the research associations provide industrial liaison services to their member firms. The Department is arranging with the Scottish Office for a study of the special needs of small firms in Scotland for research and technical information.

Absenteeism of Workers In Small and Large Organizations

UNDER the title "Size and Morale: Preliminary Study of Attendance at Work in Large and Small Units" (pp. 44; London: Acton Society Trust, 1953; 3s. 6d.), the Acton Society Trust has issued a report covering three inquiries: one in the coal industry, one in a large industrial group and one in a large retail organization controlling 230 stores throughout Great Britain. All three inquiries showed that, as a general rule, workers are absent from work for one reason or another more frequently in large concerns than in small ones. The trend is particularly noticeable in the coal industry; it is fairly marked in the industrial sample, and just discernible in the commercial undertakings that were studied. The investigation showed that miners in the smaller pits appeared to take much more interest in the affairs of their own pit than did men working in larger pits. Further, absenteeism and accident-rates were statistically correlated with size throughout the coal industry, and, when similar geological conditions were being worked, output per man-shift tended to be higher in small pits than in large. It is not suggested that workers' morale is necessarily worse in large than in small units: the study emphasizes that there is an urgent need for detailed descriptive studies of individual working organizations if the significance of size is to be understood fully, and that investigations into the social and human factors are likely to provide the most valuable clues. Studies of the social effect on absenteeism of the distance of travel of the worker to his place of employment and of the effect of the number of hierarchical stages in the line of communication between the employee and the local manager are suggested as promising lines of inquiry.

Trends In Trade Union Organization

In 1894, the year when the Webbs published their first edition of the "History of Trade Unionism", the Labour Department of the Board of Trade recorded 1,314 trade unions with a total membership of 1,530,000. By the end of 1951 the number of unions had fallen to 704 and the total membership had reached 9,480,000. In 1894 the average number of members per union was 1,160, whereas in 1951 it was 13,452, a twelvefold increase. These broad statistical changes clearly indicate that trade unions have grown larger; but what they do not reveal is the degree to which union membership is concen-

trated in relatively few of them. In 1951 seventeen unions with a membership in excess of 100,000 accounted for 6,305,000 members. Although trade union membership is to-day highly concentrated, it is spread through a far greater range of occupations and industries than it was sixty years ago, when it was drawn in the main from a few that had become reasonably well organized during the nineteenth century. These changes in trade union structure and organization are described by P. C. Roberts in an article based upon considerable investigation and much practical experience in a recent issue of the Unilever magazine, *Progress* (43, No. 240, autumn 1953).

Investigations in Physics published in Russian and other Slavonic Languages

Among the resolutions passed during the General Assembly of the International Union of Pure and Applied Physics held in Copenhagen during 1952 was a recommendation that action should be taken to publish papers reviewing the work done in various fields of experimental and theoretical physics and published only in Russian and other Slavonic languages. As a result, the organization of this task was undertaken by the permanent secretariat of the Abstracting Board of the International Council of Scientific Unions, and a number of reviews of work done in the U.S.S.R. and countries of Eastern Europe have been prepared, each containing a bibliography on the subject in question. A supplementary number of the Italian journal of physics *Il Nuovo Cimento* is being prepared (Supp. to Vol. 10, Series 9) and will be available shortly, containing the following reviews: Soviet physics (J. Turkevich); mechanical twinning (R. W. Cahn); recent Soviet work in the field of crystallography (A. L. Mackay); crystallography in Eastern Europe (A. L. Mackay); théorie de la liaison chimique (M. Magat); sur les travaux de magnetisme en U.R.R.S. (S. Rosenblum); recent research on superconductivity in the U.S.S.R. (D. Shoenberg); Polish physics (W. J. Swiatecki); recent research on cosmic radiation in the Soviet Union (G. Wataghin); and recent Russian work on liquid helium (J. Wilks). The number of copies will be necessarily limited, and those wishing to order a copy who are not regular subscribers to *Il Nuovo Cimento* should write at once to either Nicola Zanichelli, Editore, Via Imerio N.46, Bologna, or to Prof. G. Polvani, Direttore, Via Saldini N.50, Milano. The price of the Supplement will be about 2500 lire.

Classification of Vegetation

In a search for objective methods to be used in the classification of vegetation, D. W. Goodall (*Austral. J. Bot.*, 1, 3, 435; 1953) has directed attention to the concept of fidelity as originally advanced by a Swiss school of plant ecology. This idea is bound up with the concepts of characteristic species; that is, plant communities were classified according to the presence or absence in them of small groups of 'characteristic' species much more common in one particular community than in any other. In the present investigation Goodall has attempted to express the concept of fidelity quantitatively. A new index of fidelity is described, based on the ratio of frequencies for the species in two communities. The importance of significance tests in determining characteristic species is emphasized. The value of a species as indicator of a particular

community is taken as the ratio of the frequency in that community to the frequency elsewhere within the area studied. An index to express this is proposed. The value of discriminant functions in enabling vegetation samples of uncertain affinities to be allotted to one of several possible communities is demonstrated. An example is given in which this technique has been used to determine whether one community can be regarded as intermediate between two others, or has special features of its own.

Radio Industry Council Premiums for Technical Writing

THE Radio Industry Council has awarded premiums of 25 guineas each for articles on radio published in the public technical press during 1953 as follows: G. G. Gouriet (spectrum equalization; *Wireless Eng.*, May); A. W. Keen (triode transformation groups; *Wireless Eng.*, October); A. H. Beek and A. D. Brisbane (a cylindrical magnetron ionization gauge; *Vacuum*, April 1952 and published April 1953); Dr. D. McMullan (the scanning electron microscope and the electron-optical examination of surfaces; *Electron. Eng.*, February); H. M. Davis and Miss J. E. Seaborn (a linear sweep cathode-ray polarograph; *Electron. Eng.*, August); J. R. Pollard (selective calling for radio-telephone systems; *Electron. Eng.*, December). The Radio Industry Council's Premiums for technical writing were first awarded last year by the Council for articles published in non-private periodicals during 1952, the object being to encourage the writing and publication of articles reporting technical progress and development of radio, television and electronics in Great Britain. Any writer is eligible who is not paid a salary wholly for writing and is earning less than 25 per cent of his income from fees from articles or from book royalties.

British Glaciological Society: Officers for 1954

THE following have been elected officers of the British Glaciological Society for 1954: *President*, G. Seligman; *Vice-Presidents*, Rt. Rev. W. L. S. Fleming, Bishop of Portsmouth, W. V. Lewis, K. Sandford and J. M. Wordie; *Chairman of the Committees*, V. E. Fuchs; *Secretary*, Mrs. H. Richardson (c/o Scott Polar Research Institute, Lensfield Road, Cambridge); *Honorary Treasurer*, T. H. Best; *Honorary Editor of the Journal of Glaciology*, G. Seligman (Little Dane, Biddenden, Ashford, Kent).

South African National Committee on Geochronology

THE first meeting has recently been held of the South African Committee on Geochronology, a new body which is under the sponsorship of the South African Council for Scientific and Industrial Research. The Committee has been formed "to take note of developments in this field in South Africa and overseas, and to do all it can to further them". Its members are at present: Dr. B. F. J. Schonland (*Chairman*), Dr. L. T. Nel, Dr. S. H. Houghton, Dr. E. J. Marais, Dr. D. Schreiner, Mr. R. T. Jamieson and Mr. J. D. Louw (*Honorary Secretary*).

Oil and Colour Chemists' Association: Sixth Technical Trade Exhibition

OWING to war damage repair work being undertaken at the Borough Polytechnic, the Sixth Technical Trade Exhibition of the Oil and Colour Chemists' Association will not be held there, as in former years,

but instead will be at the Royal Horticultural Society's Old Hall, Vincent Square, London, S.W.1, on the following dates and times: April 21 (3-8.30 p.m.), April 22 (2-8.30 p.m.) and April 23 (2-7.30 p.m.). One advantage of this change is that the entire exhibition will be housed in one hall. An exhibition luncheon will take place, as in former years, at the Criterion Restaurant, Piccadilly, London, W.1, on April 21, tickets (one guinea each) for this function being restricted to members of the Association and to two per exhibitor. Applications for these tickets and for copies of the exhibition brochure should be made to the General Secretary, Oil and Colour Chemists' Association, Memorial Hall, Farringdon Street, London, E.C.4, from whom all further information can be obtained.

Fourth International Conference on Electrodeposition and Metal Finishing, London

THE Fourth International Conference on Electrodeposition and Metal Finishing will be held in the Holborn Restaurant, 218 High Holborn, London, W.C.1, during April 20-24. The Conference, which is under the aegis of the International Council for Electrodeposition, will be organized by the Institute of Metal Finishing. About two dozen papers will be read, and a session of particular interest will be one at which a panel of American experts will answer questions relating to practice in the United States. An exhibition of techniques and equipment will be held in conjunction with the Conference. Further information can be obtained from the Conference Secretary at the Institute of Metal Finishing, 32 Great Ormond Street, London, W.C.1.

Royal Society Lectures

THE following arrangements have been made for Royal Society Lectures during 1954: Leeuwenhoek Lecture, by Prof. J. H. Quastel, professor of biochemistry, McGill University, Montreal, and director of the Research Institute, Montreal General Hospital, on "Soil Metabolism" (May 6); Croonian Lecture, by Sir Howard Florey, professor of pathology in the University of Oxford, on "Mucins and the Protection of the Body" (May 27); Bakerian Lecture, by Prof. A. R. Todd, professor of chemistry in the University of Cambridge, on "Chemistry of the Nucleotides" (June 17).

The Night Sky In March

NEW moon occurs on March 5d. 03h. 11m., U.T., and full moon on March 19d. 12h. 42m. The following conjunctions with the moon take place: March 11d. 13h., Jupiter 3° S.; March 23d. 02h., Saturn 8° N.; March 26d. 15h., Mars 3° N. Mercury is in inferior conjunction on March 1, after which it is a morning star but is unfavourably placed for observation during the month. Venus, an evening star, sets at 18h. 10m., 18h. 55m. and 19h. 45m. on March 1, 15 and 31, respectively. Most of the illuminated portion of the disk is visible, and the stellar magnitude is -3.4 throughout the month. Mars, a morning star, rises at 2h., 1h. 40m. and 1h. 15m. at the beginning, middle and end of the month, respectively, stellar magnitude 0.8-0.2. The great change in brightness is due to the decrease by 27 million miles in the planet's distance from the earth. Jupiter is visible throughout the night, setting in the early morning hours at 2h. 35m., 1h. 45m. and 0h. 50m. on March 1, 15 and 31, respectively, stellar magnitude -1.8. Saturn is an evening star, rising at 23h., 22h. and 20h. 55m. at the beginning, middle and end of the

month, respectively, stellar magnitude 0.6-0.5, and is easily identified in the constellation Libra a little north-west of α Libra. Occultations of stars brighter than magnitude 6 are as follows, observations being as if made at Greenwich: March 11d. 21h. 30.4m., 118 Taur. f (D); March 13d. 18h. 37.9m., 8 Gemi. (D); March 13d. 19h. 44.6m., 8 Gemi. (R); March 13d. 23h. 03.9m., 63 Gemi. (D); March 16d. 22h. 41.4 m., 83 B. Leon. (D); March 17d. 1h. 43.8m., π Leon. (D). D and R refer to disappearance and reappearance, respectively. Vernal equinox takes place on March 21d. 04h.

Announcements

THE essay subjects for this year's *Endeavour* prizes of the British Association for the Advancement of Science will be as follows: the upper atmosphere; heat of the earth; coal as a raw material; water supply; the span of life; and colour photography. Essays must be sent in by June 1 and must not exceed four thousand words. Competitors must be twenty-five years old or less on June 1 and the prizes will be 50, 25 and 15 guineas respectively, with two special awards of 5 guineas for those less than eighteen. Further information can be obtained from the Assistant Secretary, British Association for the Advancement of Science, Burlington House, Piccadilly, London, W.1.

DR. R. BRAUDE, of the National Institute for Research in Dairying, has been appointed adviser on pig research to the Agricultural Research Council. The post will only occupy part of Dr. Braude's time, leaving him free to continue active research in this field. He will also act as technical secretary to a committee which is being set up by the Council to review and co-ordinate existing research on pigs, and to propose such other work as is thought desirable.

THE Ministry of Agriculture and Fisheries and the Department of Agriculture for Scotland are offering a number of postgraduate scholarships in agricultural economics, husbandry, statistics and agricultural and dairy engineering, for the academic year beginning next October. The closing date for applications is March 15. Further particulars can be obtained from the Secretary, Ministry of Agriculture and Fisheries (Research Branch), 1-4 Cambridge Terrace, Regent's Park, London, N.W.1 (to whom residents in Northern Ireland should also apply), or the Secretary, Department of Agriculture for Scotland, St. Andrew's House, Edinburgh 1.

THE first part of *Current Chemical Papers* has now been issued by the Chemical Society (No. 1, pp. 44; 1954) and contains the titles, with authors' names and references to the original, of publications received during the whole of the previous month. The entries are classified in ten groups and cover the whole field of chemistry. There will be no index to the publication. Further particulars can be obtained from the Chemical Society, Burlington House, London, W.1.

THE final volume of "Thorpe's Dictionary of Applied Chemistry", announced by Messrs. Longmans Green in *Nature* of February 20 (Advert. Supp. p. ii), as for publication this month, will not be ready until the early summer.

ERRATUM. In the communication "Pigmentation of the Jellyfish, *Pelagia noctiluca*" (*Nature*, January 23, p. 169, par. 7, lines 8 and 9, for "but no pyrrole reaction on roasting" read "and a pyrrole reaction on roasting").

ATOMIC ENERGY RESEARCH AT HARWELL*

THE Atomic Energy Research Establishment at Harwell is responsible for research into all the problems of atomic energy except those relating to atomic weapons, which are studied at the Armament Research Establishment under Sir William Penney at Aldermaston.

The work at Harwell is mainly applied research on the development of new types of nuclear reactors and their civil applications. Two research reactors, GLEEP and Bepo, have already been built, and help was given in designing the plutonium production reactors at Risley. This work requires the solution of many chemical and metallurgical problems, and a large staff of scientists is required to study them. A by-product of the reactor programme is the manufacture of radioisotopes, and many consignments of them are now sent to assist medical, agricultural and industrial research all over the world.

Nuclear reactors are assemblies of uranium either in its natural proportions or enriched in the proportion of uranium-235, together with other materials known as moderators, in such quantities and proportions that a sustained nuclear chain reaction is established producing fissions of the light isotope of uranium at a steady rate. The moderator slows the neutrons down to thermal energies, at which they have a much greater probability of causing fission. The designer of a reactor is faced by a host of complex problems. He has to make sure that at least one, on the average, of the neutrons emitted from a nucleus undergoing fission eventually causes another fission, so that the reaction is maintained in spite of the fact that neutrons are lost by capture in the moderator and structural materials, or by escape from the reactor.

Three groups of physicists are concerned with reactor design. Theoretical workers calculate how the neutrons behave in a reactor of any specified design, and then the reactor physicists build a sub-critical reactor to confirm their predictions. The solid-state physicists estimate how well the proposed structural materials will stand up to the intense neutron bombardment inside a reactor.

The designer is very restricted in his choice of materials by the requirement that they must not capture many neutrons. The only practicable moderators are graphite, heavy water, beryllium and ordinary water. Each of these has its advantages but also its disadvantages, so the designer has to make a choice to suit the type of reactor required. Another problem is the choice of fluid to transfer the heat from the reactor to the power unit. The first British nuclear power plant will use carbon dioxide as the heat-transfer medium and graphite as the moderator.

As the reaction proceeds, the uranium-235 is destroyed by fission and almost replaced by plutonium-239 formed from uranium-238 by neutron capture. As the fission products themselves capture neutrons, there comes a time when they absorb so many that the reaction stops. It is therefore necessary that they should be removed; it is sometimes

desirable also to extract the plutonium, for it has many important uses. Several groups at Harwell are studying the complex chemical and engineering problems of the extraction and utilization of plutonium and fission products. The latter used to be regarded as waste; but now many industrial uses are being found for them.

Since radiations injurious to the human body are emitted by nuclear reactors, it is necessary to study the biological effects of atomic radiations and establish strict safety regulations. This has now been done so effectively by the Health Division at Harwell that the danger of radiation injury is negligible.

Such are some of the many problems which have arisen in the development of the first power reactor in Great Britain. Each new type of reactor brings in a new set of problems, often requiring the separation of some rare metal and the determination of its chemical and metallurgical properties. Fast reactors are now being extensively studied as they are potentially important as breeders of nuclear fuel. They use no moderator, and the reacting volume is very small, which makes the heat-transfer problems more difficult to solve. Furthermore, the neutron flux is much greater in these reactors; this intensifies the problem of finding materials able to retain their mechanical properties. To assist in these studies a materials testing reactor with a very high neutron flux is being designed at Harwell to study the behaviour of materials under intense neutron bombardment.

All these technological developments depend on the researches of the nuclear physicists, who determine the fundamental nuclear constants which have to be known before a reactor can be designed. It is very important, for example, to know accurately the average number of neutrons emitted per fission of uranium-235 or plutonium, and how they react with the materials used in building the pile.

Apart from these studies directly related to reactor development, there are many research groups at Harwell working on fundamental problems, such as the nature of nuclear forces, with no immediate practical application in view. Among the instruments used is a cyclotron which can accelerate protons to 180 MeV., and a 600-MeV. proton linear accelerator is being built. The chemists have groups working on the elements beyond plutonium, on solid-state chemistry and on radiation chemistry. All this work is done in close collaboration with the universities—an arrangement which is mutually beneficial.

Many new kinds of electronic devices which are indispensable in nuclear research are being developed, and some of these are being built in large quantities by industry for other research laboratories and for civil defence. An electronic calculating machine using transistors is being built to solve the computing problems of the theoretical physicists.

Harwell is organized into a number of divisions, each dealing with one aspect of atomic energy and composed of up to ten research groups each studying a particular problem. The work of the different groups and the focusing of the research on to special projects is arranged by a number of committees or informal working parties. Every effort is made to avoid excessive formalities and in this the administrative staff has co-operated very fruitfully.

* Summary of a lecture by Sir John Cockcroft, being the first of a series of public lectures arranged by the Atomic Scientists' Association and the Department of Extra-Mural Studies of the University of London. The complete series of six lectures will appear in the March and subsequent issues of the *Atomic Scientists' Journal*, and also as a book entitled "News and Views on Atomic Energy", to be published by Messrs. Taylor and Francis, Ltd.

MICRORADIOGRAPHY AND AUTORADIOGRAPHY

A SYMPOSIUM on microradiography and autoradiography was held on December 17, 1953, at the Institute of Physics, 47 Belgrave Square, London, by the Scientific and Technical Group of the Royal Photographic Society. Many modern scientific methods are intimately connected with photographic techniques, and it can be regarded as very fortunate that biological and medical research workers and photographic scientists were able to meet one another at such an occasion to discuss their methods and also their results.

The first part of the meeting was devoted to microradiography and gave evidence of the potentialities and limitations of the method. From recent physical and technical developments on X-ray beams from very small focal spots, new possibilities may be expected. The first speaker, Prof. G. A. G. Mitchell (Anatomy Department, University of Manchester), explored the potential uses of microradiography of biological objects, such as body tissues, leaves, seeds, fibres, hairs, insects, wings, ova, small crustacea, etc. He has tried methods of enhancing contrast by using various injections and by soaking or impregnating tissues and materials with solutions which are more-or-less radio-opaque; he has also tested material with and without preliminary freeze-drying. Prof. Mitchell came to the conclusion that in most respects microradiography is less valuable than histological and histochemical methods in investigating the structure and composition of biological objects. On the other hand, the following advantages of microradiography were stressed: much thicker sections can be examined and thus the arrangement of various structures can be traced over greater distances than is possible in ordinary histological sections 5–10 μ thick; structures containing bone or calcareous deposits can be examined without preliminary decalcification; normal or abnormal deposits of radio-opaque substances are readily detectable; and the distribution of vessels and tubules can be studied accurately and fairly rapidly by the method.

Mr. R. V. Ely (London) dealt almost exclusively with the requirements of apparatus such as 'sealed off' and 'demountable' X-ray tubes, backing and diffusion pumps, valves, vacuum gauges, high-tension and filament supply units, mains voltage stabilizers, vacuum cassettes, etc. A demountable X-ray tube developed by Mr. Ely permits easy removal of the window in order to attach an extension cylinder holding a quarter-plate at a considerable distance from the target. The apparatus can be used for photographic as well as for direct magnification; in the latter case only very small focal spots are permitted.

Whereas the first two speakers chiefly dealt with magnifications up to 500 times, the third speaker, Dr. V. E. Cosslett (Cavendish Laboratory, Cambridge), looked for magnifications of the order of one thousand diameters and above. He therefore prefers the term 'X-ray microscopy' to microradiography. Since the optical resolving-power is limited to about 0.5 μ by the wave-length of light, a higher resolving-power should be possible using X-rays of a wave-length of the order of 1 Å. As the contrast attainable is roughly proportional to the cube of the wave-length of the X-rays, practical considerations demand the use of wave-lengths of one or several angstroms (that is, 12-kV. X-rays and less are required). Four

basic methods of X-ray microscopy were suggested: the conventional contact method, where object and film are in close proximity; three other methods which entail direct magnification by means of curved crystals, by mirror reflexion and end-window X-ray tubes, respectively. The relative merits of these four methods were reviewed, and the end-window technique that has been developed by Dr. Cosslett was described in greater detail. It involves the production of an ultra-fine focus on an end-window target, using electron optical techniques. The use of very thin windows makes high X-ray intensity available from spots of the order of 1 μ in diameter. At present, Dr. Cosslett and his co-workers are attempting to obtain a focal spot of the order of 0.1 μ . High direct magnification is obtained by bringing the specimen close to the window. Several examples of Dr. Cosslett's method for examining the microstructure of biological and metallurgical specimens were shown. Photographs have been taken of living insects, in which great interest is being shown at the present time, in order to follow up radiation damage in insects when exposed to various X-ray doses.

The second part of the meeting was entirely devoted to biological autoradiography. The techniques of micro-autoradiography are mainly based on the use of stripped nuclear-track emulsions. At present the refinement of methods appears to be in the foreground of autoradiographic investigations and, in particular, a deeper insight into the problems of resolution and quantitative uptake of radioisotopes is required. Dr. S. R. Pelo (Experimental Radiopathology Research Unit, Hammersmith Hospital, London) reviewed autoradiography by discussing the possibilities and limitations of the method, the planning and design of experiments and the interpretation of the results. The incorporation of radioisotopes into chemical compounds in the organism depends on the correct choice of the chemical compound of interest and the concentration, which in turn is dependent on the sensitivity of the film material to be used. Formulae which relate the concentration in terms of micro-curies per c.c. and of half-lives of the tracer were given. An estimate of the amount required depends also on the frequently unknown distribution within the organism. It was shown, for example, that, by administering sulphur-35 as sulphate ion, it finds its way into the cells of the cartilage of the trachea and very little is taken up by the epithelial lining. After injection of sulphur-35 as *D*-methionine (³⁵S), significant accumulation of the isotope is found in the epithelial cells and only a faint trace in the cells of the cartilage. In the preparation of the specimens, special care has to be taken in regard to possible loss of radioactive compounds due to solvents and also to the possibility of the formation of artefacts that are caused, for example, by chemical interaction between specimen and photographic material. Several examples of the possible ambiguity and pitfalls in interpretation were given.

Dr. L. F. Lamerton (Department of Physics, Royal Cancer Hospital, London) discussed problems involving the resolution and sensitivity in autoradiography. In contrast to the theoretical treatment of resolution by Doniach and Pelo, Dr. Lamerton defines resolution as the distance d if the images of two uniformly active cylindrical sources of diameter d can just be resolved when the centres are separated by a distance $2d$. A table was given showing the resolution, in terms of microns, obtainable theoretically for various emulsion and specimen thicknesses

and for various distances between specimen and film. In addition there are two further factors which limit the high resolution otherwise attainable. These are the unavoidable background due to chemical fogging and cosmic rays, and the cross-fire of radiation from surrounding parts of the specimen. With reasonable precautions, the background may be reduced to about 4 grains/100 μ^2 or less. From a theoretical treatment of the cross-fire radiation (based on a relation between grain density and distance from a point source), it is shown that an autoradiograph will be recognizable above a structure of cellular dimensions only if the concentration of the activity within the structure is a number of times greater than that of the surrounding specimen. This concentration must be higher for long-range electrons, that is, greater with phosphorus-32 than with sulphur-35 or carbon-14. Dr. Lamerton referred also to a new Kodak X-ray stripping-plate which fills the gap in sensitivity and resolution between the fast X-ray film and the relatively slow nuclear-track stripping-plate.

Dr. L. G. Lajtha (Radiotherapy Department, Churchill Hospital, Oxford) described a high-resolution autoradiographic stripping-film technique adapted to smears made from human bone-marrow cultures *in vitro*. In such a smear the cells are separated sufficiently from each other to prevent 'cross-fire', and good results have been obtained by floating the emulsion at 25° C. on distilled water for 4-6 min. The autoradiographs were stained after processing to facilitate recognition of the individual cells. The method is sensitive enough to detect and localize as little as 20-30 phosphorus-32, or 30-50 sulphur-35, atoms per cell.

Experiments on the mechanism of deoxyribonucleic acid synthesis as measured with phosphorus-32 and adenine (¹⁴C) were described. Experiments on sulphate (³⁵S) uptake have shown that uptake of inorganic sulphate (³⁵S) and its incorporation into a substance related to the chondroitin sulphates is a specific function of the myeloid cells in the bone marrow.

THE BOSE INSTITUTE, CALCUTTA

THE thirty-sixth anniversary meeting of the Bose Institute took place on November 30, 1953, when Dr. N. K. Bose, director, River Research Institute, delivered the sixteenth Acharya Jagadish Chandra Bose Memorial Lecture on "The Role of Silt and Sand in Multipurpose River Valley Projects".

Dr. D. M. Bose, director of the Bose Institute, in presenting his report on the working of the Institute for the past year, said that completion of many important projects commenced during the past few years was being delayed for want of funds. He mentioned that early this year the Institute had acquired a plot of forty bighas of good agricultural land at Shamnagar, near Barrackpur, for erection of an experimental station for certain fundamental investigations in plant sciences which the Institute proposes to undertake. The Institute had to obtain a loan of Rs. 60,000 for this purpose. For the erection of necessary residential quarters and laboratory buildings and for electric installation and for fencing the estate about Rs. 1 lakh will be required.

The investigations which the Institute has been carrying out during the past few years on the action of X-radiation in producing mutations in a few economic plants have obtained a certain amount of

recognition, and the Institute has, on invitation from the National Institute of Sciences of India, submitted a five-year scheme, which may be extended by another five years, of fundamental investigations on the mutagenic action of different kinds of radiations on plants. The latter will be selected mainly for their suitability for genetic studies.

Preliminary investigations started during the past year have disclosed that the beta-radiation from radioactive phosphorus, which is selectively absorbed in plant nuclei, is a very convenient tool for inducing mutation in plants; for example, with this method, new types of effects are being obtained in certain varieties of jute plants in addition to those obtained with the same kind of plants after irradiation trials with X-rays extending over many years.

At Mayapuri, Darjeeling, a plant pathological laboratory was begun about three years ago as an experimental measure. Already valuable work has been started on the breeding of new hybrids of potatoes resistant to several virus and fungal infestations, using locally available potatoes as one of the parents and imported resistant strains as the other. This work is being undertaken in co-operation with the West Bengal Seed Potato Farm at Rungbul, near Darjeeling. The Institute has already done some good work in detecting the presence of potato wart disease, hitherto not known to occur in India, in one of the plots at Rungbul sown with an imported variety of potatoes known as Eureka. This observation when published in *Science and Culture* attracted the attention of the Ministry of Agriculture, Delhi, and resulted in a visit to Darjeeling of the director of potato research and the deputy director of plant protection for inspection of control measures. Studies of other potato diseases of bacterial origin have resulted in the receipt for examination from different parts of India of similar infected potato tubers. Without more financial assistance the Institute cannot indefinitely maintain the Plant Pathological Laboratory, which will be compelled to close.

Mayapuri is also being developed as a centre for cosmic ray research. On a request from the Council for Scientific and Industrial Research, India, a scheme with detailed plans and estimates for erection of a laboratory and workshop for cosmic ray research has been submitted. There will also be accommodation for guest workers who may come to Mayapuri for cosmic ray work.

The Institute has received a new grant from the Board of Research on Atomic Energy for investigations on the use of radioactive isotopes of carbon and phosphorus for studying photosynthesis and the mutagenic action of beta-rays of phosphorus. In a recently formulated five-year plan of research the Institute has included a proposal for the study of photosynthetic utilization of solar rays as a method for food and power production and of its economic feasibility.

The microbiology department has received a grant from the Council for Scientific and Industrial Research, India, for the production of antibiotics isolated from *Streptomyces* spp. which has some remarkable bactericidal properties.

Besides these new schemes, the Institute is continuing to receive the usual grants-in-aid from the Board of Research on Atomic Energy, the Central Jute Committee, the Central Oil Seeds Committee, the Cotton Committee of West Bengal, I.C.A.R. grant for weed control, and the B.O.C. grant for paleobotanical research.

HIGH SPEED RECORDERS

- Single and multi-point instruments
2, 4, 8 or 16 points.
- Sensitivity 500 microvolts
full-scale on single point.
1 millivolt on multipoint.
- Accuracy. $\pm 0.5\%$ of scale span for
spans of 1 millivolt and above.
- Full-scale deflection in 2 seconds.
- Chart. 6 speeds—1, 2 or 3 inches
per hour. 1, 2 or 3 inches per
minute by instant change gear box.

*Manufacturers of Pneumatic and Electrical Instruments for measurement, control and recording
of Temperature, Flow, Liquid Level, Specific Gravity, Pressure in Science and Industry; Vacuum
Pumping and Measuring Equipment, etc.*

Colloidal MoS₂

ACHESON COLLOIDS LIMITED, makers of 'dag' dispersions, announce that as well as being the world's largest manufacturers of colloidal graphite they are now large-scale producers of the outstanding, new, solid lubricant Molybdenum Disulphide.

All interested in the following subjects are specially invited to write for our MoS₂ technical leaflets:—

Metal-forging, -drawing and -extrusion,
High-speed machinery,
High-temperature and high-pressure
lubrication,
Dry lubrication.

The recent developments in MoS₂ techniques are in line with advances in many other branches of industrial colloid technology. May we put you on our mailing list for all such news?

'dag' dispersions of Colloidal Graphite, Molybdenum Disulphide, Silver, Titanium Dioxide and other substances are available.

ANOTHER EXAMPLE OF EFFICIENCY

WATER JACKETED INCUBATOR

Accurate temperature control up to 80° C. with a low internal temperature gradient.
(Available in 3 standard sizes)

COOLING COIL
Provision can be made in the water jacket by a system of built-in cooling-coils to permit the incubator to operate at temperatures below ambient. Minimum operating temperature about 2 or 3° C. higher than available cooling water temperature.

The scope of research of the Institute both in pure and applied sciences is increasing, and additional capital and recurring grants are required for the completion of the development and equipment schemes in hand and for providing the workers of the Institute with adequate scales of pay and for increased cost of maintenance and research. Applications have been made to the Central and State Governments for additional grants.

COUNTY DETAILS OF THE CENSUS OF WOODLANDS, 1947-49

THE Forestry Commission Census Reports, Nos. 1 and 2, dealing respectively with the woods less than and more than five acres in extent (the latter including hedgerow and park timber) have already been reviewed in *Nature* (August 8, p. 240, and October 3, p. 616), and they have now been supplemented by three further issues—Census Reports Nos. 3, 4 and 5—giving the details for the Welsh, Scottish and English counties respectively as deduced from the Census of Woodlands 1947-49*. The details are given by counties for these larger woods, the additional figures being for areas only, as the information is not available for standing volume or annual growth. Distribution as between the Forestry Commission and Private Woodlands is shown in all the nine tables given in standard form for each county. National totals are usefully given even where this means some duplication of information given in Report No. 1.

In addition to showing the break-down of the totals of Report No. 1 into county figures, fuller detail is given in certain other respects. Thus the age-class structure of the several categories of high forest is shown by decades for 0-40 years and by twenty-year periods between 40 and 80 years, followed by two classes for the older woods, namely, 80-120 and more than 120 years. This detail will be useful for many purposes owing to the big differences in immediate utility, rate of growth, current yields as thinnings, etc., between crops of different age, which are such that the grouping into only two classes above and below 40 years is inadequate.

The fuller detail for the areas under the different tree species is similarly very necessary since the distribution is so widely different from county to county—and here, too, age-classes are differentiated, while separate tables are given for pure stands only as well as for mixed and pure stands together. Thus the basic data are now available for determining what area of spruce or poplar might be available in any section of the country from which to draw supplies for existing or contemplated industries.

Information is also given for six more of the less commonly grown conifers and six more hardwoods, revealing how little we still have of them, even of poplar (1,466 acres, though this is only for woods more than five acres in extent). It can similarly now be seen where the scrub and devastated woodlands are concentrated and how much of these areas is thought to be suitable for economic management.

These reports are in foolscap size, the counties being arranged in alphabetical order, and the tables

* Forestry Commission. Census of Woodlands 1947-49: Woods of Five Acres and Over. Census Report No. 3, Welsh County Details; pp. vii+90; 4s. 6d. Census Report No. 4, Scottish County Details; pp. vii+187; 10s. 6d. Census Report No. 5, English County Details; pp. vi+270; 12s. 6d. (London: H.M.S.O., 1953.)

are reproduced in a clear and convenient form so that reference is easy. The only regret is that one has to be content with area data where one usually needs volumes.

OXIDATION OF PHENYL-HYDRAZINES IN THE PRESENCE OF OXYHÆMOGLOBIN AND THE ORIGIN OF HEINZ BODIES IN ERYTHROCYTES

By DR. G. H. BEAVEN

Medical Research Council Spectrographic Unit,
The London Hospital, E.1

and DR. J. C. WHITE

Department of Pathology (Haematology), Postgraduate
Medical School of London, W.12

THE occurrence in phenylhydrazine (Ph.NH.NH₂) poisoning of a hæmolytic anemia with Heinz inclusion bodies in the erythrocytes is well known. Such inclusions also form rapidly in normal erythrocytes on *in vitro* incubation at 37° with phenylhydrazine¹. With destomatized oxyhæmoglobin solution and excess of various substituted phenylhydrazines, the oxyhæmoglobin is degraded and precipitated as a 'green hæmoglobin' with composition similar to that of the Heinz bodies, while the hydrazine undergoes oxidation. The process is strictly aerobic, though at low oxygen tension other changes in the oxyhæmoglobin may occur with the more reactive hydrazines, such as choleglobin formation without any formation of green precipitate. The aerobic oxidation of long-chain, unsaturated fatty acids is also catalysed by oxyhæmoglobin, which is decomposed and converted to colourless substances². In these reactions, oxyhæmoglobin is "the catalyst of its own destruction"³, while acting as the last link in the utilization of molecular oxygen⁴.

Oxidation of Arylhydrazines

Experiments were performed in Dreschel bottles, and volatile products of oxidation swept over by air or oxygen into ethanol. In the presence of oxyhæmoglobin, excess phenylhydrazine and acetylphenylhydrazine (Ph.NH.NH.CO₂Me) yield as end-products nitrogen and benzene, the latter being detected by its ultra-violet absorption spectrum.

When present in excess, the oxyhæmoglobin is itself oxidized to methæmoglobin (MetHb), and with 2:4-dinitrophenylhydrazine and *asym*-diphenylhydrazine this reaction alone occurs, no green hæmoglobin being formed.

Benzene is not formed from phenylhydrazine or acetylphenylhydrazine in the presence of reduced hæmoglobin (Hb) and nitrogen, and similarly with methæmoglobin only a trace of benzene is formed, but a much larger production occurs on admission of oxygen. With oxyhæmoglobin, less benzene is formed under anaerobic than under aerobic conditions. Spectroscopic evidence suggests that reduction of oxyhæmoglobin or methæmoglobin precedes degradation. Similar aerobic reactions, with insoluble 'green hæmoglobin' production, occur with phenylhydrazine-*p*-sulphonic acid; with *o*- or *p*-nitrophenylhydrazine, the volatile oxidation product is nitrobenzene.

Fig. 1. Neutral acetone extract of 'green hemoglobin' precipitate from aerated oxyhaemoglobin-acetylphenylhydrazine system. (a) —, Neutral acetone extract, diluted 1:10; (b) ---, neutral acetone extract diluted 1:10 with 30 per cent aqueous pyridine, followed by dithionite

The two curves have been separated slightly on the absorbance scale for increased clarity (a) —, As (a), diluted 1:100; (d) ---, as (b), diluted 1:100

The scales of all the figures are linear in wave-number ($\bar{\nu}$) and absorbance (optical density)

Fig. 2. (a) —, Iron-free green pigment from acid-treated 'green hemoglobin' precipitate in chloroform; (b) —, as (a), diluted 1:5; (c) ---, as (b), in 30 per cent hydrochloric acid; (d) -.-.-, blue-green 'biliverdin-type' pigment from acid-treated 'green hemoglobin' precipitate, in 30 per cent aqueous pyridine

Arylhydrazines are readily oxidized by atmospheric oxygen⁸, but only traces of benzene or nitrobenzene have been obtained from aerated aqueous suspensions of phenylhydrazine or *p*-nitrophenylhydrazine. These findings point to an oxidation-reduction system between the oxyhaemoglobin and the arylhydrazine, with hydrogen transfer from the latter to molecular oxygen, while the oxyhaemoglobin undergoes irreversible changes. The oxidation of acetylphenylhydrazine by potassium ferricyanide is also catalysed by oxyhaemoglobin with appreciable production of benzene and conversion of the pigment to 'green hemoglobin' precipitate.

The oxidation by molecular oxygen may involve hydrogen peroxide, but the rate of oxidation of acetylphenylhydrazine does not appear to be affected by 0.0025 *M* potassium cyanide added to depress catalase activity. (S. Brenner and A. O. Allison (*Experientia*, 9, 381; 1953) have since pointed out, however, that many toxic substances producing Heinz bodies are themselves catalase inhibitors, and suggest that catalase inhibition may be the first step in the production of Heinz bodies in intact erythrocytes.) The system arylhydrazine/oxyhaemoglobin possesses certain

similarities to the aerobic phenylhydroxylamine/oxyhaemoglobin system of Keilin and Hartree⁹, in which nitrosobenzene is formed and co-ordinates with the haem of the haemoglobin. When oxyhaemoglobin is aerated in the presence of excess nitrosobenzene, we find that the purple complex decomposes and a typical 'green haemoglobin' precipitate forms.

The intermediate products have not been characterized in our work, with the exception of phenol. Benzene is the ultimate product of oxidation of phenylhydrazine or acetylphenylhydrazine, possibly arising via the diimide $\text{PhN}=\text{NH}$, but the yield is small under our conditions.

The 'Green Haemoglobin' Precipitates

The insoluble 'green haemoglobin' is complex, containing haems and other iron-containing pigments bound to denatured globin. The relationship to choleglobin and denatured choleglobin haemochrome¹⁰ is not clear; the former can often be detected, but may not be related directly to the formation of the 'green haemoglobin', and indeed is most abundant in poorly-oxygenated systems where no green precipitate is formed. Certain features of the green precipitate formed in the presence of acetylphenylhydrazine have been clearly established:

(1) Neutral acetone extracts a haem with bands at 400, 557 and 625 $\text{m}\mu$ (Fig. 1), giving a typical

Fig. 2. (a) —, Green pigment liberated from 'green hemoglobin' precipitate by peptic digestion, in water; (b) —, 1:5 dilution of (a); (c) ---, solution (b) after dithionite

haemochrome spectrum with pyridine and dithionite with maxima at 418, 525 and 557 m μ . More haem is extracted by acid acetone.

(2) The haem is a protohaem, since protoporphyrin and mesoporphyrin (ratio c. 10:1) are the only porphyrins isolated after treatment of the 'green haemoglobin' with sodium amalgam. Normal haemoglobin gives the same porphyrins in similar ratio under these conditions¹⁰, but in much higher yield.

(3) Protein-bound haem is most abundant during the early stages of the formation of green precipitate, when the colour is predominantly brown-green. Later, the haemochrome reaction is weaker, but iron-containing green pigments are still present. Secondary changes lead to very firm binding of the pigments to the protein, so that acid acetone no longer extracts them completely, and the precipitate loses its solubility in aqueous urea solution, though remaining soluble in glacial acetic acid.

(4) The green pigments are liberated as water-soluble peptides by peptic digestion. A Soret-type absorption band occurs (Fig. 2) at 410 m μ , moving to 423 m μ on dithionite reduction. An inflexion at 605 m μ is the only other feature in the visible region. Ferric iron is rapidly liberated from the green pigment in 2.5 N hydrochloric acid (cf. ref. 11), leaving chloroform-soluble green pigments which still possess an absorption band at 410 m μ (Fig. 3).

(5) Derivatives resembling verdohaemochrome¹² were not obtained. None the less, the presence of acid-labile iron and the persistence of a Soret-type absorption band suggests that the porphyrin ring has not been opened, and that the protein-bound green pigment is not of the bile-pigment type. Most attempts to obtain bile pigments from the green precipitate, either directly or after treatment with hydrochloric acid or acetic acid, have failed. However, on one occasion hydrochloric acid-acetone extracted a blue-green pigment with biliverdin-type band at 705 m μ , but an anomalously weak band at 410 m μ (Fig. 3).

Heinz Body Anaemia

The relationship of the 'green haemoglobin' precipitate to Heinz bodies in erythrocytes was studied in a case of poisoning by acetylphenylhydrazine, and also in erythrocytes incubated with this compound. Heinz bodies remained attached to the stroma after laking the erythrocytes. Denatured globin was demonstrated by staining after susa fixation in a mixture of orange G and aniline blue at pH 3; the bodies stained orange, as does the haemoglobin in intact erythrocytes, whereas the stromal protein was blue¹³. Stromal lipid, which stained with sudan black, was present at the periphery of the bodies.

Repeated washing of the residue after laking yielded a brownish-green mass of Heinz bodies. Pyridine extraction gave the pyridine haemochrome spectrum (λ_{max} 418, 525 and 557 m μ), intensifying with dithionite. Extracts with 0.1 N hydrochloric acid, ethanol and 0.2 N potassium hydroxide had Soret-type absorption bands at 398, 402 and 407 m μ respectively. The soluble oxyhaemoglobin from the patient's erythrocytes was normal and no methaemoglobin or choleglobin was detected.

In the various extracts of experimentally produced 'green haemoglobin' precipitate, benzene was frequently detected (Fig. 2). It is noteworthy that in anaemia of swine caused by phenylhydrazine, Lawson *et al.*¹⁴ observed typical haemolytic anaemia in

five animals, but a fatal aplastic anaemia in the sixth, the features of which resembled benzene poisoning.

We wish to thank Dr. E. R. Holiday for spectrographic facilities and Dr. E. A. Johnson for assistance with some of the experimental work.

INFLUENCE OF TEMPERATURE AND SOIL WATER CONTENT ON THE SEEDLING BLIGHT OF MAIZE

By JOHN L. HARPER

Department of Agriculture, University of Oxford

IN northern temperate climates, a serious problem in maize cultivation is that the growing season is usually too short to allow the grain to ripen¹. It is therefore desirable to plant as early as possible. However, early plantings seldom give a good stand because in the germination phase the grains are attacked by pathogenic fungi. Varieties of maize differ in their resistance to this 'seedling blight' and a variety of laboratory techniques have been devised to assess the resistance of newly bred varieties. These tests usually involve planting the grain in jars or trays of soil, which are then exposed to low temperatures, usually between 7° and 10° C. for a period of 8-10 days. After this treatment the grain is allowed to germinate at some favourable temperature, usually 20-25° C. The proportion of grains which fail to germinate gives a measure of the resistance to seedling blight or what is sometimes loosely called 'cold hardness'².

The length of the exposure and the temperatures to which the grains are subjected vary from worker to worker, and apart from the pioneer work of Dickson³, who studied infection by *Gibberella zeae*, there has been no previous attempt to investigate in a detailed manner the comparative effects of exposure to different temperatures or to determine the influence of soil moisture content on the liability of maize grains to pathogenic attack in the soil. It was felt that a study of the conditions affecting seedling mortality of maize might give some information on the general behaviour of soil-borne pathogens at various soil moistures and temperatures.

For these experiments one variety of maize was used, namely, Virginian White Horsetooth, which is grown fairly widely as a forage crop in Great Britain and which was known to be liable to damage in cold

Fig. 1. The germination of White Hornetmouth maize in soils of various moisture contents and at various temperatures. Soil moisture level in Figs. 1 and 2 is expressed as percentage increase in weight of dry maize grains after incubation in soil at 20° C. for 24 hr.

springs. Soils for this experiment were sampled from plots on which maize had been grown for two years previously. After collection in the late summer the soil was spread on a clean barn floor and turned every day for five days and then divided into four parts. To one part enough water was added to bring the soil to its sticky point. The amount of water needed to do this was measured, and a half and a quarter of this amount were added to two of the remaining samples. The fourth sample was maintained dry. Each soil sample was well mixed and allowed to stand for six hours to allow the water to be evenly distributed. Each sample was then mixed again, and sub-samples were placed in 1-lb. jam jars and sixteen maize grains were planted in each jar. Eighty of these jars were prepared, twenty from each soil sample, and each set of twenty was distributed at random between four incubators at 1°, 8°, 20° and 30° C. For each soil moisture/temperature combination there were five jars, and one of these was withdrawn after 3, 6, 9, 12 and 15 days. After treatment the grains were removed from the soil, first washed in 1/1,000 mercuric chloride and then in changes of distilled water and placed individually on agar slopes of maize meal agar. The tubes were now incubated at 20° C., and after fourteen days incubation the number germinated was recorded (a seed was said to have germinated if the main root had emerged from the sheathing coleorhiza). Germination was tested in this experiment on agar slopes so that the types of fungi invading the grains could be investigated; but these particular results of the experiment will be published elsewhere. A series of controls was prepared in which grains taken directly from the original sack were surface washed as in the experimental samples, and placed directly on agar slopes.

The moisture content of the soil was determined by placing weighed samples of maize grains in additional jars of the soil samples, and after twenty-four hours incubation at 20° C. the grains were removed, cleaned with a dry cloth and reweighed. The increase in weight of the grain samples gave a measure of the availability of the soil moisture and is comparable with the method described by Shull for using seeds in the determination of the 'surface forces' of the soil⁴. For the determination of soil moisture, grains of Wisconsin 275 maize

were used, as this variety gave very consistent values. Losses in weight of the grains due to respiration in the twenty-four-hour incubation period were negligible in comparison with the experimental error.

When the treated jars were sampled, it was found that many of the grains had germinated in the soils at high temperatures and moisture contents. The mean percentage germination over all sampling occasions is shown in Fig. 1.

The grains which had not germinated in the jars at the time of sampling were transferred to agar slopes at 20° C. and the subsequent failure to germinate was determined; the mean results over all sampling occasions are given in Fig. 2. Analysis of variance of the results of this experiment show that both time and soil water content have significant effects on the mortality ($P < 0.01$). The effect of temperature as a main effect was not significant. However, the interaction of temperature and soil moisture was highly significant ($P < 0.001$); other interactions were negligible. Clearly, soil moisture is of overriding importance in determining the extent of mortality, and the effect of temperature is mainly to produce an interaction with this main effect. Inspection of Figs. 1 and 2 shows clearly that damage is least where the treatments result in rapid germination. The greatest mortalities are obtained when the temperature and moisture conditions are such that germination just fails to take place. From this pattern of results it is concluded that the pathogens are affected in the same general manner as the host, but are more tolerant in both moisture and temperature requirements.

It is of interest that the two peaks of greatest damage, 8° C. at moisture content IV and 30° C. at moisture content II, were formed at very different rates. At 30° C. maximal damage had been attained by the sixth day; but at 8° C. the degree of injury was small at first but was still increasing after fifteen days. It is probable that the slowing up of the rate of kill is an indication of the rate at which the soil dried. (Determination of the soil moisture content of the soils after fifteen days showed that the soils had lost water during the experiment, but the relative moisture contents of the samples were scarcely changed except where rapid germination had occurred.)

The results of this experiment have an especial significance in a programme of maize breeding in

Fig. 2. The influence of various soil moisture and temperature combinations on the viability of maize grains

Fig. 3. The influence of fungicide seed dressing on the viability of maize grains exposed to various temperatures in wet soil. ●—●, Treated with fungicide; ○—○, not treated with fungicide; ○—●, reduction in mortality due to fungicide treatment.

which the cold testing of varieties is undertaken. Hitherto little attempt appears to have been made to control the moisture content of the soils employed, and it is our experience that this is the most important single factor which will influence the reaction of the varieties under test. Owing to the grave difficulties involved in maintaining a known and constant soil suction pressure, it is suggested that this cold testing should be undertaken in loosely packed soils, in open-bottomed fibre pots 6 in. tall, which stand in shallow trays of water throughout the experimental period.

In a further experiment a wide range of temperatures was employed, while, in addition, the effects of seed dressing with a commercial preparation of tetramethyl thiuram disulphide were included. The soil water content was maintained by the method previously described. Samples of White Horse-tooth maize grains with and without previous seed dressing were sown in open-bottomed pots of soil standing in trays of water $\frac{1}{2}$ in. deep and incubated at 0°, 5°, 10°, 20° and 30° C. After ten days treatment the pots were all transferred to a temperature of 20° C.; the ultimate germination (inclusive of that during and after treatment) is presented in Fig. 3. It is clear that mortality decreases steadily with a rise in temperature from 0° to 20° C. and that the subsequent rise in temperature to 30° C. has little further effect. The extent of mortality prevented by fungicide dusting increases from 0° to 5° C. and then falls off and becomes negligible at 20° and 30° C. This experiment therefore allows a distinction to be drawn between the damage due to micro-organisms and that which may be called a true cold injury.

These experiments demonstrate clearly that the 'cold test' for maize must be carefully controlled if important and hitherto little-studied variables are to be eliminated. They also make it clear that a cold test of the rigid form used in these experiments could be of the greatest value in assessing the merits of fungicides.

I am grateful to Prof. G. E. Blackman for his interest in this work and his stimulating criticism.

[Dec. 24.]

THE PERIODIC TABLE AND ITS APPLICATIONS

By DR. S. I. TOMKIEFF

King's College (University of Durham), Newcastle upon Tyne

THE fundamental structural pattern of the periodic table of the elements is a network composed of two sets of lines corresponding respectively to periods and groups. This network is the result of the transformation of the linear array of elements, arranged in order of their atomic numbers into a bi-linear combinatorial system, with one set of lines corresponding to cut segments of the original linear array, and the other to similar periodic terms. The points of intersection of the lines of the network correspond to elements, but because of the unequal length of the periods not all these points are occupied. Actual geometrical distances between the nodal points occupied by the elements are of no significance, as we are dealing here with a network in which incidence (position) is the important factor and not congruence (measure). The real metric of the periodic table is the electron-distance. The group lines in each period are separated by one electron-distance, the consecutive period lines by one 'core-electron number' distance.

The fact that the periodic table is a topological combinatorial system, based on incidence, means that it can be distorted or projectively transformed as long as the collinearity of points and the concurrence of lines remain invariant. In this way we can have many types of the periodic table, all projectively related among themselves and all topologically equivalent. The usefulness of any given form of the periodic table depends on its degree of conformity to certain requirements. It should demonstrate the periodicity of the structure and the properties of the elements, it should be continuous, it should be completely visible and it should mirror the structure of the atom. The three principal types of the periodic table satisfying all or some of these requirements are: (1) rectilinear (Newlands, 1864; Mendeleeff, 1869), (2) helical (Béguyer de Chancourtois, 1862) and (3) spiral (Baumhauer, 1870).

Periodicity is possessed by all these three types; but type 1 lacks continuity, while type 2 lacks perfect visibility. Type 3, the spiral periodic table, clearly possesses the first three requirements and it will later be shown to possess the fourth. It is also admirably suited for service as a co-ordinate network for the purpose of contour mapping, and the main purpose of this article is to demonstrate this particular fact.

The periodic spiral used in this article is a modification of B. K. Emerson's "Helix Chemica" (1911). This shows clearly the contrast between the short and the long periods. In its present modification geochemically important elements—carbon and silicon—are placed in a central position.

The method of mapping over the periodic spiral used as a co-ordinate net is the normal cartographic method for contour maps, the data being any kind of numerical values associated with the elements. These data may be grouped under three heads: (1) properties of elements; (2) properties of compounds; and (3) composition of aggregate bodies. Such a geometrization of tabular values offers many advantages. These maps allow us to survey the distribution of the values of any measurable single

Fig. 1. Map of the magnetic susceptibility surface

property among the elements, to correlate properties among themselves and with the structure of the atom, and finally, to study the composition of aggregate bodies and to compare these with one another.

In what follows I have tried to show briefly some of the possible uses of the three principal types of maps.

(1) Properties of Elements

Maps of surfaces representing the distribution among the elements of such properties as electro-negativity, ionization energy, specific gravity, atomic volume, melting point, boiling point and atomic and ionic radii are to be published elsewhere. So, for the purpose of illustrating the method of cartography, I have selected the map of magnetic susceptibility. The data for the construction of this surface have been obtained from Prof. L. F. Bates's "Modern Magnetism", and all figures refer to measurements taken at or near normal temperature. Describing these surfaces, I will use freely geographical analogies as being generally understood.

The map of the magnetic susceptibility surface (Fig. 1) shows that, with two exceptions (zirconium and oxygen), all the elements are localized within two distinct and separate areas, namely, the paramagnetic 'highlands' and the diamagnetic 'lowlands'. Zirconium forms a 'tarn' in the 'highlands', while oxygen forms a considerable 'peak' in the 'lowlands'. On the other hand, the ferromagnetic elements—gadolinium, iron, cobalt and nickel—form 'peaks' in the 'highlands'. With the exception of the elements of groups 1a and 2a and aluminium and zirconium, all the paramagnetic elements are confined to the region occupied by the elements belonging to the 'transition series' of the long periods (groups 3a to 8a), namely, those elements which in their structure are characterized by the *d*-level electrons.

(2) Properties of Compounds

Numerical data relating to compounds can be mapped over the periodic spiral only in the case of compounds possessing a common component (element or radical). Thus, we can map properties of such compounds as simple oxides, simple carbonates, simple sulphates, and such like, by using the metallic components of these compounds as the index elements of the periodic spiral.

As examples of surfaces showing the distribution of a given property among the compounds, I have chosen the distribution of the heat of formation among simple oxides. The data for the construction of this surface have been obtained from "The Thermochemistry of the Chemical Substances" (1936) by Bichovsky and Roessini. The heat of formation of compounds is usually given per gram-molecule. As the oxides have a great variety of type of molecules, for the purpose of uniformity the heat of formation has been recalculated by me as 'per double bond' of oxygen atom, in calories.

The contour map (Fig. 2) was constructed on the data related to pure compounds. The surface of heat of formation is characterized by a north-west high region, from which stretches a long west-east ridge, occupied by such minerals as corundum (Al_2O_3), rutile (TiO_2), quartz (SiO_2) and cassiterite (SnO_2).

If we take another group of minerals, such as sulphides, for example, we shall see that the heat of formation surface has a shape similar to the heat of formation surface of the oxides, but that the characteristic ridge is half the height of the characteristic ridge of oxides and is also displaced to the 5a-3b line of the periodic spiral.

Like solubility, melting point or hardness, the heat of formation of compounds may be taken as the index of strength. It is interesting, therefore, especially for a mineralogist or geochemist, to obtain such surfaces for various groups of minerals, so as to be

Fig. 2. Map of the 'heat of formation of oxides' surface

Fig. 3. Map of the 'average composition of granite' surface.
Contours: 0—(1)—10—80.
Leading elements (in atomic percentages): O, 63; Si, 24; Al, 4;
Na, 2½; H, 2; K, 2

able to evaluate their relative strength as influencing their position in the paragenetic succession. As compared with the heat of formation surfaces, the hardness surfaces are somewhat of analogous shape. Thus the hardness surfaces are characterized by dominant ridges like the heat of formation surfaces. The ridge of the hardness surface of oxides, for example, stretches from corundum (Al_2O_3) via quartz (SiO_2) to cassiterite (SnO_2), while in the case of the hardness surface of sulphides the ridge stretches from laurite (RuS_2) via pyrite (FeS_2) to zinc blende (ZnS).

(3) Composition of Aggregate Bodies

In this case it is not the parameters or numerical values of properties that are mapped, but the percentages (weight, volume or atomic percentages) of elements contained in various bodies, such as organisms, rocks, geospheres, meteorites or even the cosmos. An example of such a surface is that of the average composition of granite.

The 'granite' surface (Fig. 3) is in the form of a broken crater-rim, somewhat distorted by the pulling out of the spiral which forms its co-ordinate net. If we use the evenly coiled Archimedean spiral as the basis of the projection, the broken crater-rim or atoll analogy becomes much clearer. Placed on this crater-rim we have three hills, each corresponding to a pair of the leading elements: oxygen-hydrogen hill, silicon-aluminium hill and sodium-potassium hill with magnesium-calcium extension. Such a grouping is most significant from a geochemical point of view, mainly because it reflects the leptological structure of alkali feldspar, the major constituent of granite. The three hills correspond to the three principal structural units of feldspar, namely, (1) oxygen tetrahedra, with (2) silicon-aluminium cores, and (3) sodium and potassium atoms filling up the

'holes' between the oxygen tetrahedra. The other constituent mineral of granite is mica and quartz. Muscovite mica is made of the same elements as potash feldspar with the addition of the hydroxyl group (OH), and quartz is made of interlinked oxygen tetrahedra alone. Oxygen tetrahedra also form the principal structural units of other silicate minerals. In this way the whole of the lithosphere may be visualized as an aggregate of oxygen tetrahedra, with silicon and aluminium forming their cores and sodium, potassium, calcium, magnesium and iron occupying cavities between them.

In the course of this article reference has been made to a supposed relationship between the periodic table of the elements and their atomic structure. One of the qualities of the spiral periodic table—and one, moreover, which is peculiar to the spiral—is that it is not only a periodic table of the elements but also a symbolic representation—a mirror or a map—of the electronic structure of the atom. This contention may be challenged, but it becomes quite clear if we visualize the three-dimensional atom with its nucleus and its concentric electronic shells as represented in a plane by a central blob for the nucleus and concentric circles for electronic shells. A spiral can easily be formed from these concentric circles by traversing them by a radial line and displacing one out edge and of each circle one unit distance to the next circle. Place the appropriate number of points along the coils of this spiral, the number corresponding to the saturation number of electrons in successive numbers of electronic shells—2, 8, 8, 18, 18, 32, . . .—and we have the model of the atom in the spiral, which is at the same time a periodic table with the length of each period expressed in terms of the number of elements in it, as determined by the Tomkeieff¹ formula:

$$X = \frac{(2n + 3 + (-1)^n)}{8},$$

in which X is the length of the period in terms of the number of elements present in it and n is the principal quantum number of the outer shell of the atoms belonging to this period. The periodic spiral thus mirrors the electronic structure of the atom. This means that whatever data relating to the elements we plot over the periodic spiral by using it as a co-ordinate net, we place directly in a functional relation with the atomic structure the two sets of co-ordinates representing (1) period lines of the elements or the core types of the atomic structure, and (2) the group lines of the elements or the periphery types of the atomic structure².

The maps of the surfaces given and discussed in this article represent a small sample of the cartographical method in which data relating to chemical elements are used for the construction of contours over the periodic spiral used as a co-ordinate net. The surfaces thus constructed do not depend on hypothetical presuppositions but represent true correlation between sets of observed numerical data and the periodic table, and as the periodic table in its turn mirrors the electronic structure of the atom, the correlation is between the observed numerical data and the structure of the atom. The surfaces are true invariants of Nature.

Pile Production of Radioisotopes by Threshold Reactions

A GREAT advantage of production of radioisotopes by threshold reactions (n,p) and (n,α) , relative to neutron capture (n,γ) , is that the radioisotope can be separated chemically from the target material, and hence be obtained in high specific activity, in principle completely carrier-free. The rate of threshold reactions in the pile, however, is much smaller in general than that of capture reactions, not only because of the low cross-sections for neutrons in the MeV. range but also because of the low flux of neutrons of that energy in the pile. As measurement of the small yields of such reactions is often difficult, especially for long-lived radioisotopes, it is very useful to be able to predict approximate yields in advance. An example is furnished by the reaction $^{54}\text{Fe}(n,p)^{54}\text{Mn}$, recently discussed by Stafford and Stein¹; in this case some experiments had indicated production of the 324-day manganese-54 by pile neutrons, whereas others showed none. The most recent experiments², however, utilizing samples enriched in iron-54, definitely established the reaction with a cross-section for fast neutrons of 11 millibarns (10^{-27} cm.²). It is the purpose of the present communication to point out that the approximate yields for threshold reactions in the pile can be predicted, and to illustrate the method for $^{54}\text{Fe}(n,p)^{54}\text{Mn}$ as an example.

A systematic survey of threshold reaction cross-sections for fission neutrons was carried out by Hughes, Spatz and Goldstein³ in 1946. Whereas the original purpose of the measurements was to investigate the shape of the fission neutron spectrum at high energies, the present well-known spectrum⁴ allows the results to be used to systematize the reaction yields. It is found⁴ that the threshold reaction cross-section for fission neutrons is proportional to the integral of the fission spectrum above an 'effective energy', E_{eff} , which is a few MeV. higher than the threshold energy for the reaction, E_T . The quantity $E_{\text{eff}} - E_T$, which rises rapidly with atomic number, is simply related to the penetrability of the outgoing particle and the fission spectrum shape. Results for (n,p) reactions only are given in Fig. 1, where the cross-sections, multiplied by $10/A^{1/3}$ to correct for variation in nuclear size, are plotted against E_{eff} and compared with the integral of the fission spectrum (solid line). The average deviation of the experimental points from the curve is about a factor of two, although the cross-sections themselves cover a range of 3,000-fold. The results of Fig. 1 indicate that the cross-section for the (n,p) reaction for a neutron energy at which the penetrability becomes unity is approximately proportional to πR^2 (with R the nuclear radius), actually being about $0.1 \pi R^2$, as compared to $0.2 \pi R^2$ for (n,α) reactions⁴.

For the $^{54}\text{Fe}(n,p)$ reaction, E_T is given by the mass difference manganese-54 - iron-54* (0.71 MeV.) minus the $n-p$ mass difference (0.78 MeV.), or -0.07 MeV. The quantity E_{eff} for this reaction is then found to be 4.2 MeV., and $\sigma 10/A^{1/3}$ is obtained from Fig. 1 as 7 mb. The cross-section itself is 9.5 mb. ($A^{1/3} = 13.5$), in surprisingly good agreement with the 11 mb.

Fig. 1. Measured cross-sections of (n,p) reactions for fission neutrons as a function of effective energy compared with the integral of the fission neutron energy spectrum

measured by Stafford and Stein¹. Although Fig. 1 refers to cross-sections for unmoderated fission neutrons, the cross-sections for pile neutrons as well are principally a result of unmoderated fission neutrons, for which the flux near a uranium fuel rod is approximately equal to the thermal flux⁴. It is interesting that the curve of Fig. 1 works well for the iron-54 reaction even though the experimental points used to normalize it were all for lighter elements.

The practical value of Fig. 1 and the corresponding curve for (n,α) reactions arises from the fact that approximate yield predictions can be made and thus complex and lengthy measurements avoided. The cross-sections will, of course, decrease rapidly for higher values of Z ; for example, for E_T near zero, the cross-sections for (n,α) and (n,p) reactions decrease from 16 and 80 mb. respectively at $Z = 10$, to 0.01 and 1.5 mb. at $Z = 40$. Large variations in E_T occur for light elements, but these become smaller, and affect the cross-sections less, as Z increases.

Tidal Forces and the Formation of Hurricanes

MAY I raise the following question: "Do tidal forces affect the formation of hurricanes?" If one examines the changing direction of the tidal force due to the sun and a moon, near new (or full) on an August day, say, as this force acts on a small element of air located at a point south of the sub-solar latitude and north of the equator, one finds the tidal force would tend to make the atmospheric element move in a counter-clockwise direction as viewed from above. Furthermore, as the sun moves southward in August and early September, the latitudes where the highest atmospheric tides would be expected (here considered semi-diurnal), would fall alternately north and south of the equator, the successive points on either side approaching the equator. Might there not be one time at which the separation of these two latitudes would correspond to a natural frequency of oscillation of the atmosphere? If these arguments have any validity, the hurricanes in the North Atlantic should show an increase in number shortly before September 23 and a decrease shortly after that date.

The first date given for each tropical storm in the years 1900-49 inclusive was taken from Tannehill's "Hurricanes" (eighth revised edition, Princeton University Press, 1952) and the frequencies noted for a number of intervals in the hurricane season. The results are shown in Table 1.

Table 1

Interval	Number	Number per week
August 24-31	32	23
September 1-7	27	27
September 8-14	40	40
September 15-23	33	28
September 23-30	20	17.5
October 1-7	27	27
October 8-14	26	26

To determine whether the change from 40 for September 8-14 to 17.5 (per week) for September 23-30 was statistically significant, the fifty-year period was broken into five ten-year blocks and averages and variances determined. It was found that the change corresponded to a 2 per cent level of significance, that is, that this might happen by chance once in fifty times.

Also, if tidal forces play an important part in the formation of hurricanes, they should leave their mark on year-by-year statistics. Here I elected to break up the eighteen-year interval into four periods of four, five, four and five years. Then the number of hurricanes in each four-year period was increased by 25 per cent so that the comparison might be made on a uniform five-year basis. The results, again based on Tannehill, are shown in Table 2.

Table 2

Interval	Number	Number per 5 years
1900-1906	24	30
1906-1910	35	35
1911-1914	16	20
1915-1919	28	28
1920-1923	19	23.8
1924-1928	34	34
1929-1932	22	27.5
1933-1937	61	61
1938-1941	27	33.8
1942-1946	44	44

The average (on a five-year basis) for the four-year intervals was 27.2 ($\sigma = 4.8$). For the five-year intervals, the average was 40.4 ($\sigma = 11.5$).

I am aware that the tidal forces are not large; but I would suggest that in meteorology the result is not always proportional to the force that triggers the action. I suggest that an investigation of atmospheric tides and their effects on the formation of hurricanes would be worth while.

Irradiation of Transistors

THE effect of stored holes in transistors has been reported by Meacham and Michaels¹, and the importance of the effect in the design of switching circuits was stressed by speakers in the discussion following a paper by Williams and Chaplin². Briefly, good circuit design often necessitates operating a transistor in the condition where the collector current is limited by an external resistance; in this condition the time of fall of collector current upon cessation of emitter current is found to be much slower than when the collector current is limited only by the current gain of the transistor. It is the time of fall of collector current which determines the maximum switching speed of a transistor.

During some irradiation experiments on commercial point-type transistors in the Harwell pile, we have found that if a transistor is given a radiation dose of about 10^{14} neutrons/sq. cm., the time of fall of collector current from the value limited as described above is decreased, with little or no deterioration of the other parameters of the transistor. Curves of collector current against time after the sudden cessation of an emitter current of 3 m.amp. are shown in Fig. 1 for the same transistor before irradiation and 2 hr. afterwards. The transistor used had a current gain of 2.2, so that at least 6.6 m.amp. of collector current was available; the collector current was limited to about 5.4 m.amp. by an external resistance.

Measurements have been repeated at intervals over a period of four weeks from the time of irradiation and have shown little change. Measurements after

Fig. 1. Fall of collector current following cessation of emitter current

150 cycles of temperature from ambient to 70° C. have also indicated that the change in time of fall of collector current due to irradiation should be permanent.

A sample of mono-crystalline germanium has also been irradiated with a dose of 10^{14} neutrons/sq. cm. A rise in resistivity from 2.03 ohm cm. to 2.24 ohm cm. and a decrease in hole life-time, measured by a modified light-spot system³, from 1.6 μ sec. to 0.6 μ sec. were observed, with little change in hole mobility. In addition, two samples of 6 ohm cm. material have been measured by the Post Office Research Station, Dollis Hill. Decreases in hole life-time from 50 μ sec. to 6 μ sec. and from 6 μ sec. to 1 μ sec. have been reported.

The most abundant expected transmutations⁴ are as follows:

		No of atoms produced
$^{76}\text{Ge} (\alpha, \gamma) ^{76}\text{Ge}$	$\xrightarrow{11 \text{ 4 days } \beta^-}$	^{76}Ga
$^{76}\text{Ge} (\alpha, \gamma) ^{76}\text{Ge}$	$\xrightarrow{83 \text{ min. } \beta^-}$	^{76}As
$^{76}\text{Ge} (\alpha, \gamma) ^{76}\text{Ge}$	$\xrightarrow{12 \text{ hr. } \beta^-}$	^{76}As
	$\xrightarrow{40 \text{ hr. } \beta^-}$	^{76}Se
		$1 \times 10^{11}/\text{c.c.}$

These yields of impurities are low compared with those normally present, and no changes with time since irradiation consistent with these half-times have been observed.

We therefore believe that the decreased time of fall of collector current is caused by the production of recombination centres, such as lattice defects, in the bulk material.

These and similar experiments are being continued. We should like to thank the Chief Superintendent, Services Electronics Research Laboratory, for measurement facilities on germanium placed at our disposal.

A Solid State Transformation in Tetra-acetyl-D-ribofuranose

It has been reported¹ that two modifications of 1,2,3,5-tetra-acetyl-D-ribofuranose can be prepared, one (A) melting at 56–58° C.; the other (B) melting at 85° C. It was also reported that a transformation in the solid state took place from A to B which was catalysed by the presence of B, and that no laboratory which was once contaminated by B had been able to repeat the preparation of A.

In a discussion with Dr. George B. Brown, of the Sloan-Kettering Institute for Cancer Research, New York, N.Y., it was suggested that X-ray data be taken for these two materials, even though a detailed structural analysis might not prove immediately to be feasible.

Several months later, a single crystal suitable for X-ray work was obtained from a sample of the A-material prepared and sent to us by Dr. Irving Goodman, of the Wellcome Research Laboratories, Tuckahoe, N.Y. The X-ray study was carried out by Weissenberg and Buenger precession techniques. There are two molecules in a monoclinic cell of the space group $P2_1$, the dimensions of which are:

$$a = 12.49 \text{ \AA}, b = 5.58 \text{ \AA}, c = 11.12 \text{ \AA}, \beta = 97^\circ 45'.$$

Weissenberg multiple-film photographs for the layers $h0l$, $h1l$, $h2l$ were taken with copper radiation. Precession photographs using copper and molybdenum were taken of the $h0l$, $h1l$, $0kl$ and $1kl$ layers.

The single crystal of the A-material mounted for X-ray examination remained stable for seven weeks. At the end of this period crystals of the B-modification were obtained from Dr. Brown and were also mounted for X-ray examination. The A-crystal remained stable in the same room with the B-crystals for about three days. Some of the B-material was powdered and sprinkled over the A-crystal at the start of a Laue photograph exposure. The resulting film indicated that the A-crystal had transformed completely to the B-material in 5–15 min. The transformed material, a fine powder of the B-substance, formed an opaque block in the external shape of the original A-crystal. It had been hoped that the transformed powder would show some preferred orientation with respect to the original A-structure, but this was not apparent.

Weissenberg and precession photographs of the stable B-material identified the space group as $P2_12_12_1$ with four molecules in a cell of dimensions:

$$a = 7.50 \text{ \AA}, b = 13.66 \text{ \AA}, c = 15.33 \text{ \AA}.$$

No systematic collection of intensity data for the B-material has been undertaken.

It is interesting to note that the molecular volume increased by about two per cent during the transformation (A: 383.9 $\text{\AA}^3$; B: 392.5 $\text{\AA}^3$).

At the present time, we do not contemplate detailed analysis of the data we have obtained. We shall be glad to furnish further information on our results to those who are interested.

It is a pleasure to thank Dr. Brown for his suggestion and discussion of this investigation and for the material which he supplied us. We are also very grateful to Dr. Goodman for the sample of the rare A-material.

Static Electrification of Petrols

It is well known that petrols flowing down a tube acquire a quite considerable electrostatic charge, and it is perhaps less well known that the addition of a reasonable quantity of alcohol reduces this charge to insignificant proportions¹. Some recent experiments on the effect of small quantities of alcohol reveal, however, very puzzling results. The pure petrol always acquires a positive charge and the addition of slightly more than 1 per cent of alcohol reduces the charge to zero; but what is remarkable is that the addition of a little more alcohol produces a

negative charge until about 8 per cent, after which the charge is negligible.

This general result is true (though the magnitude of the charges vary) for all the different brands of petrol tested and also for toluene. It is true whether the flow is steady or turbulent, and is unaffected by altering the materials of the tube. In fact, the same thing occurred when the mixture ran through muslin or a filter paper, in both of which cases the charges were far higher than when the mixture was running down a metal tube.

As an example, 20 c.c. of 82 octane aviation spirit run down a Dural tube 40 cm. long and 5 mm. diameter acquired when pure a charge of +1.5 e.s. units; 2 per cent of alcohol reduced this to zero, and from 2 to 8 per cent the charge was negative, rising to a maximum of -22 e.s. units for 4 per cent and thereafter decreasing. Thus the charge is not only reversed but also becomes much larger than for the unadulterated petrol.

The only part of the phenomenon which is readily understandable is the disappearance of the charge for the higher concentrations. The petrol itself has an enormous electrical resistance, but the addition of alcohol much reduces it and the charges acquired by contact with the tube then leak back to it before they can be carried away by the emerging liquid. The specific resistance of the aviation spirit was of the order of 5×10^{12} ohms per cm. cube. The addition of each successive 2 per cent of alcohol reduced the resistance by a factor very close to 10, so that the 8 per cent solution had ten thousand times the conductivity of the spirit.

It would be wise, however, to hesitate before theorizing as to the cause of the reversal of sign of the charge, as the following experiment shows that things are more complex than might appear at first sight.

If a mixture is chosen giving the negative charge, and the same specimen is poured repeatedly down the same tube, the negative charge decreases each time, finally becoming positive and ending up for some concentrations at a value rather higher than the unadulterated petrol produces. This surprising change in the charge is not the result of the mixture altering in any way by evaporation or otherwise, for the resistance remains unaltered.

It would appear, therefore, that the negative charge is not due to the alcohol-petrol mixture, but to minute quantities of some third substance which is removed by the ions transferred in each run down the tube. Whether this third substance is the small amount of water always found in alcohol is uncertain.

Effect of Hydrogen Peroxide on the Analysis of Organic Peroxides

In many combustion products, hydrogen peroxide forms a large part of the peroxidic products isolated¹. It is therefore worth recording some observations on the interference caused by hydrogen peroxide in the analysis of such mixtures as hydrogen peroxide and methyl hydroperoxide.

It has long been known² that alkyl hydroperoxides, unlike hydrogen peroxide, do not liberate the stoichiometric

metric quantity of iodine from acidified potassium iodide. It has now been found that the extent to which they react depends, not only on the time, and on the type and amount of catalyst, but also on the concentration of any hydrogen peroxide which is present.

The estimations were carried out in an atmosphere of oxygen-free nitrogen in stoppered flasks in the absence of light. The test solution, containing hydrogen or methyl peroxide, or both, was added to 25 ml. of 2 N hydrochloric acid together with 1 c.c. of 50 per cent potassium iodide. Any catalyst was added at this stage. Nitrogen was again passed, and the flask stoppered. A blank run, free of peroxide, was also carried out. The catalyst, either ammonium molybdate or ferrous sulphate, was added in the form of three drops of a 2 per cent solution. After a given time, the iodine was titrated against 0.01 N sodium thiosulphate. The following results are typical of many others which were obtained.

In the presence of 6.43 ml. of 0.01 N hydrogen peroxide, the iodine liberated by a constant amount (10.4 ml. of 0.01 N) of methyl hydroperoxide was increased by 16 per cent after 1½ hr. by the addition of ferrous sulphate, while ammonium molybdate had practically no effect during this time. However, it was found that, if the concentration of hydrogen peroxide was increased thirty times, the iodine liberation of the methyl hydroperoxide was increased by 57 per cent after 3 hr., and by 28 per cent after 15 hr. It is clear that the indicated concentration of organic peroxide depends both on the ratio $H_2O_2/ROOH$ and on the time, as is shown schematically in Fig. 1. Evidently, the interpretation of iodometric estimations of peroxide mixtures must be made with great caution.

A parallel effect, also dependent on the relative concentrations of the peroxides, has been observed in the reaction of the lower peroxides with potassium permanganate in acid solutions³.

Possible Existence of a Transition Point between β - and γ -Sulphur

γ -SULPHUR, the metastable monoclinic modification first described crystallographically by Muthmann¹, is frequently obtained when a thin film of molten sulphur between a slide and cover slip is caused to solidify by chilling. Using such preparations, we have recently made some preliminary determinations of the linear rates of transformation of this form into both α - (rhombic) sulphur and β -sulphur, the monoclinic modification stable above 96°, as an extension of previous studies of the linear rate of transformation of β - into α -sulphur²⁻⁴. The smoothed results are shown in Fig. 1, which also gives those for the β - to α -transformation. The three curves intersect at A, B and C, and although the temperature co-ordinates given for these points, namely, 12°, 55° and 75° respectively, can only be regarded as approximate at present, their existence is not in any doubt, since they have been confirmed by a number of observations of the relative rates of the transformations on slides on which all three forms were present.

The existence of a point A at which the rates of transformation of β to α and of γ to α are equal raises the interesting question as to whether there is a transition point between β - and γ -sulphur at or near this temperature. This possibility is suggested by the following considerations. In certain theories already put forward to account for the linear rate of polymorphic transformations⁵, the rate may be expressed as a function of the free energy change, the temperature, and the vapour pressure of one of the two modifications. Thus the expression proposed by one of us (N.H.H., *ibid.*, p. 160) may in its simplest form be rewritten as:

$$v_{\beta\alpha} = \text{const. } p_1 [\exp(-\Delta G/RT) - 1], \quad (1)$$

where $v_{\beta\alpha}$ is the rate, p_1 is the vapour pressure of the stable form, and the other symbols have their usual significance. Again, Dunning's equation (*ibid.*, p. 157) may be put in the form:

$$v_{\beta\alpha} = \text{const. } p_1 \cdot \exp(-\Delta G/RT) \cdot \exp[\text{const.}/(\Delta G \cdot RT)]. \quad (2)$$

Fig. 1

These alternative forms are obtained by using the relationships:

$$p_1 = \text{const.} \exp(-L_1/RT);$$

$$-\Delta G = q[(T_0 - T)/T_0] = RT \ln(p_{\beta}/p_1),$$

where L_1 is the latent heat of sublimation of the stable form, q is the heat of transformation, T_0 the transition temperature, and p_{β} is the vapour pressure of the unstable form. The constants in (1) and (2) depend only on the properties of the stable form.

On this basis, we have for the β to α and γ to α transformations:

$$v_{\beta\alpha} = F(\Delta G_{\beta\alpha}, T, p_a),$$

$$\text{or} \quad \Delta G_{\beta\alpha} = H(v_{\beta\alpha}, T, p_a), \quad (3)$$

$$\text{and also} \quad \Delta G_{\gamma\alpha} = H(v_{\gamma\alpha}, T, p_a), \quad (4)$$

where F and H signify 'function of'.

The two functions (3) and (4) are of the same form and contain the same constants since the stable form (α) is the same in both cases.

For the γ - to β -transformation, we may write:

$$\Delta G_{\gamma\beta} = J(v_{\gamma\beta}, T, p_p),$$

where J signifies a function which will contain different constants from those in (3) and (4), since the more stable phase is now β .

$$\text{Now} \quad \Delta G_{\gamma\beta} = \Delta G_{\gamma\alpha} - \Delta G_{\beta\alpha};$$

so that if $v_{\gamma\alpha} = v_{\beta\alpha}$, $\Delta G_{\gamma\alpha} = \Delta G_{\beta\alpha}$ and $\Delta G_{\gamma\beta} = 0$, that is, a transition point exists at this temperature between the γ - and β -forms.

This treatment, however, takes no account of adventitious factors such as the mosaic block size of the unstable form or the difference in densities of the two forms, which may affect the rates of transformation of β to α and γ to α to different extents (see, for example, reference 3, p. 1112, for discussion of the possible effect of mosaic block size), so that equality of the rates at a certain temperature does not necessarily mean that the free energies of the β - and γ -forms are the same at this temperature. It does, however, suggest that they may be equal at a temperature near this.

The simplest experimental test of the existence of a $\gamma\beta$ -transition point would appear to be to see whether a reversal in the direction of movement of the $\gamma\beta$ -interface occurs at low temperatures; but this test has failed because at temperatures below 40° no movement whatsoever of this interface can be detected (at least down to -15°, the limit of our observations) even under a high-power microscope over a period of some weeks. The very high temperature coefficient of this transformation at temperatures above 40°, which corresponds to an apparent activation energy of about 150,000 cal. per mole (curve BC below B), however, is just what would be expected if there were a transition point not too far below this temperature. General theoretical considerations based on the fact that above a transition point both molecular motion and 'driving force' (that is, free energy change) increase with rise of temperature, and also experimental observations, for example, on the α - to β -transformation in sulphur above 96°, support this.

The phase transformations in sulphur are markedly accelerated when it is contaminated with carbon disulphide, and in films prepared from such material we have found that the temperature of the $\alpha\beta$ -transition point is not altered within the limits of accuracy (about 2°) of the hot stage used for our observations. This suggests that the carbon disulphide adds another phase as well as another component to the system, and this phase appears to be a liquid layer at the interface, since under the microscope bubbles can be seen moving about in this region as the reaction proceeds. If a $\gamma\beta$ -interface is established in such contaminated sulphur, observable movement at low temperatures now occurs; but at all temperatures down to -18° (the lowest attainable for microscopic observations with our present arrangements) the direction of the transformation is still γ to β . Thus the transition point, if it exists, is probably below this temperature.

Point C (Fig. 1) represents a somewhat similar case to that just discussed, for here the rates of transformation of γ to α and γ to β are equal, and the well-established transition point between the α - and β -forms exists at the not far distant temperature of 96°. The difference from the previous case is that the reactant phase (γ) is the same in the two transformations, whereas at point A it is the resultant phase (α) which is the same.

This work will be described and discussed in more detail in a further publication. It is also intended to attempt determinations of the vapour pressures of the β - and γ -forms down to low temperatures. This should provide conclusive evidence of the existence or otherwise of a transition point between these forms.

A Rapid Gasometric Method of Analysis for 'Reducing' Sugars and Other Carbonyl Compounds

ANALYSIS for reducing sugars generally involves oxidation under highly disruptive conditions with an alkaline reagent. As a consequence of the oxidative fragmentation of the sugars, the stoichiometry of the reaction is not simple, and it is necessary to employ closely controlled concentration and temperature conditions. The interpretation of the results requires the use of extensive empirical tables. Since the reducing equivalence of the various mono- and di-saccharides is not the same, an additional dimension of uncertainty is introduced into the procedure for the analysis of mixtures of reducing sugars.

Employing aqueous solutions of sodium borohydride for the reduction of 'reducing' sugars to the corresponding polyols, we have been able to carry out the rapid determination of reducing sugars at acidities of pH 7 and higher. Sodium borohydride solution is standardized by measuring the volume

of hydrogen gas evolved when the solution is made acid. The sugar solution is treated with an aliquot of the sodium borohydride reagent, and after completion of the reduction, the excess of reagent is determined by acidification, etc., as in the standardization. The difference in volume of hydrogen evolved is equivalent to the amount of 'reducing' sugar. By collecting the hydrogen over water in a very simple apparatus, we have found that one mole of hydrogen is utilized for the reduction of one mole of glucose, fructose, galactose, lactose or glucosamine with an accuracy of better than 1 per cent. Complete reduction is achieved in 20-30 min. at room temperature, or in less than one minute at the boiling point. Although aqueous sodium borohydride solutions are stable at room temperature, aliquots are most conveniently pipetted at 0° C.

Since this analytical method has many obvious applications in organic, biochemical and clinical analyses, it was considered advisable to make a preliminary report. Detailed results relating to sugar analysis, and analysis for carbonyl compounds and derivatives in general will be published later.

The Girard Reaction

Girard and Sandulesco¹ developed a method now known as the 'Girard reaction' for the isolation of small amounts of ketosteroids such as the sex hormones from natural products. Aldehydes and ketones in the mixture are converted into water-soluble hydrazone derivatives by treatment with the 'Girard P' or 'T' reagent, and the non-carbonyl compounds are removed by extraction with a non-polar solvent like ether. The ketone complexes are rapidly decomposed with mineral acid; but the aldehyde derivatives are claimed to be stable except in the presence of a large excess of acid and formaldehyde.

Recently, in an investigation of the compounds responsible for the so-called 'cardboard' flavour in skim milk, acetaldehyde was observed in 'ketonic fractions' isolated by these methods.

A study of the literature showed that Girard aldehyde complexes are not as stable as generally believed, for Lederer and Nachmias² were able to decompose some of them with hydrochloric acid after 12-14 hr. at room temperature giving 80-90 per cent yields of heptaldehyde, citral, *m*- and *p*-hydroxybenzaldehyde, 3,4-dihydroxybenzaldehyde and piperonal.

We were interested in saturated and unsaturated aliphatic aldehydes and ketones, and studied the stability of the 'Girard P' complexes of acetaldehyde, crotonaldehyde, propionaldehyde, butyraldehyde, isovaleraldehyde and *n*-heptaldehyde and acetone, methyl ethyl ketone, mesityl oxide and methyl *n*-amyl ketone. In all cases the decomposition of the Girard complex with *N*/2 sulphuric acid was found to be almost instantaneous.

It seems that the Girard reaction, while it often fails to separate aldehydes and ketones, may be suitable for the separation of carbonyl from non-carbonyl

compounds. In many cases the liberated aldehydes and ketones can be extracted as soon as the mineral acid is added.

Anthocyanins in Bananas

THE inflorescence of the banana bears female flowers at the base and male flowers apically. At each node is a cluster of flowers subtended by a brightly coloured bract, and it is upon the anthocyanins of these bracts that most of the results summarized below are based. The pigments were extracted in 1 per cent hydrochloric acid and examined in the test-tube and by paper chromatography. A picrate which was isolated from one species yielded glucose only on hydrolysis. Definition of the glycosidal types awaits determination of the sugar residues in other purified samples. After hydrolysis, the anthocyanidins were determined by means of chromatography in the Forestal solvent¹ and in butanol-2N hydrochloric acid² used separately, or jointly for a two-way separation.

The anthocyanidins. Six anthocyanidins were found, namely: pelargonidin, cyanidin, peonidin, delphinidin, petunidin and malvidin. Bract colours vary correspondingly from scarlet to deep purple or violet. Specific occurrences were as follows.

(1) Pelargonidin-cyanidin mixture: *Musa coccoinea* (one clone examined).

(2) Cyanidin-delphinidin mixtures: *M. lateralis* (one clone), *M. balbisiana* (ten clones), *M. velutina* (one clone).

(3) Partly methylated cyanidin-delphinidin mixtures (that is, mixtures of cyanidin, peonidin, delphinidin, petunidin and malvidin in various proportions): *M. acuminata* (twelve clones).

(4) Methylated cyanidin and delphinidin (peonidin and malvidin in various proportions): *M. ornata* (one clone), *M. violascens* (one clone) and an undescribed species from Assam (two clones).

Several anthoxanthins are present and their occurrences also show signs of being related to taxonomy.

Special interest centres on *M. acuminata* as the most variable species and the most important from the point of view of origins of edible bananas³. Two-way chromatograms of the anthocyanidins of eleven clones were made, and each paper was scored by two independent observers for relative intensity of the various pigments; the whole series was repeated and the results for one pigment (malvidin—more or less arbitrarily selected) were analysed, thus:

Item	D.F.	M.S.	V.R.	P
Clones	10	79.31	69.5	0.1 per cent
Replicates	1	6.57	5.76	5 per cent
Observers	1	5.12	4.49	—
Clones × replicates	10	3.77	3.30	5 per cent
Clones × observers	10	0.71	—	—
Replicates × observers	1	1.64	—	—
Error	10	1.14	—	—

There are real differences between clones, though the clones × replicates interaction shows that the

proportion of malvidin varied slightly as between samplings. There is excellent agreement between the scorings of the two observers. Thus, it may be suggested that the anthocyanidins could be estimated by measurement of optical density of the spots.

The clones of *M. acuminata* which were used came from various parts of the Far East between Java and Burma; between these extremes there is a cline of bract colour from red in the south to dull purple in the north. This cline is an expression of changing proportions of the anthocyanidins (Fig. 1); delphinidin increases to northward and, simultaneously, the degree of methylation also increases. Probably delphinidin derivatives have increased under natural selection for blueness and methylation has followed under natural selection for stability.

Edible bananas have, broadly speaking, the pigments expected on taxonomic grounds. Thus, cultivated varieties of *M. acuminata* have (with one interesting exception) partly methylated mixtures of cyanidin and delphinidin, and varieties allied to, but not necessarily wholly derived from, *M. balbisiana* have no methylation.

Ontogeny of pigmentation. The male bud of the banana is composed of a short flower-bearing axis covered with tightly imbricate bracts. The outside bracts are the oldest and are fully coloured; successively younger bracts are smaller and paler and at about bract number 9 colour disappears. Now this bract series represents an ontogenetic sequence, and it is therefore possible to follow the development of pigmentation from inception to maturity. The photograph (Fig. 2) shows the results of one experiment; the white bracts on the right contained leucocyanidin and leucodelphinidin; as visible colour appeared so methylated pigments also appeared, and at maturity the anthocyanins were glycosides of peonidin, malvidin, cyanidin and delphinidin. It is not possible here to determine with certainty the relative contributions of the products of hydrolysis of unmethylated leuco-substances and aglycones of the corresponding visible pigments. However, judging by the comparative intensities of the various anthocyanin and anthocyanidin spots, the leuco-substances (as revealed by this method of extraction) had almost disappeared from the mature

Fig. 1. Geographical distribution of anthocyanidins in bracts of *Musa acuminata*. Solid lines, proportion of delphinidin derivatives; dotted lines, proportion of pigments methylated.

Fig. 2. Ontogeny of anthocyanidins in a male bud of *Musa sapientum*, clone Langot A. Mature bract (No. 1) on the left, Nos. 2-7 successively younger and more lightly pigmented; on the right, immature colourless bracts containing leucocyanidin (cyanidin marker, cy) and leucodelphinidin. 'Meth', methylated pigments, malvidin appearing first, peonidin later but more abundantly.

bract. Malvidin appeared several days before peonidin, when the two, as in this experiment, were present together. This can be seen in the photograph and was proved in another experiment by two-way chromatography.

The elegant seriation of the male bud, the relatively large size of the bracts and the difference in times of appearance of different pigments all combine to indicate this as very favourable material for investigating the biosynthesis of the anthocyanins. Both the search for possible precursors⁴ and the experimental approach, of supplying synthetic precursors to genetically acyanic varieties, would be feasible. Furthermore, the possibility of being able to approach the problem of methylation is particularly attractive⁵.

Leucocyanocyanidins. Leucodelphinidin⁶ and leucocyanidin are almost universally present in bracts, flowers, fruits, sheaths and leaves of all bananas. They are especially abundant in green fruits; the great quantities of this material available at once suggest bananas as an excellent source for structural and biochemical investigations, since quantities of the order of 5 kgm. of dried material could quite easily be obtained.

A fuller account of this work will be published elsewhere. My thanks are due to Dr. E. C. Bate-Smith, Dr. W. G. C. Forsyth and Mr. K. De Witt for much help.

An Inhibitor of the Lysis of *Staphylococcus aureus* by Bacteriophage

UNDILUTED phage lysates of certain strains of *Staph. aureus* (type 75B) but not of others (type 69) have been shown by us to inhibit the propagation of a wide range of staphylococcal phages¹. To throw light on the nature of this inhibitor we have carried out the following experiments.

Fresh lysates were produced by plate propagation of phage 75B on *Staph. aureus* PS75B, as described by Williams and Rippon², and filtered through 'Gradocol' membranes of pore diameter 55 μ , 83 μ and 140 μ . The filtrates were spotted on a plate freshly inoculated with phage and *Staph. aureus* 31A as for propagation. After incubation the plates showed diffuse lysis, with disks of staphylococcal growth at the sites inoculated with filtrate from the membranes of 83 μ and 140 μ pore diameter, but not at the sites where filtrate through pore diameter 55 μ had been inoculated. Lytic phage was present in filtrates from the 83 μ and 140 μ membranes, but none was found in the filtrate from the 55 μ membrane. The inhibitor was therefore carried on particles of the same order of size as the phage particles.

We next compared the heat sensitivity of lytic and inhibitory components of the phage 75B lysate. 1-ml. amounts of the lysate were heated for 10 min. at 42°, 47° and 52° C., samples being taken at 1-min. intervals, and tested for inhibition and lysis. We found that the inhibitor was destroyed after 2 min. at 52° C., but was unaffected after 10 min. at 42° C. and 47° C. Plaque counts from the same samples titrated for viable phage showed that no significant reduction in lytic power occurred after 10 min. at 52° C.

These experiments suggest that the phage inhibitor may be carried on phage particles, but that the properties of lysis and inhibition can be dissociated by heat, the former persisting at temperatures which destroy the latter.

Effect of Nickel Versenate on Oat Plants

IRON versenate is now being widely used for supplying iron in plant nutrition studies¹, and it seems likely that the use of versenates of essential micro-nutrients will be extended to horticultural and agricultural practice. Ferric potassium versenate has been used here for two years as a source of iron for oats, sugar beet and tomatoes, and has proved superior to ferric citrate, especially where the pH of the nutrient solution is greater than 6.0. It is not clear whether the complex molecule itself is absorbed or whether the iron is removed at the root surface by a contact-exchange mechanism, as has been suggested by some workers².

Nickel toxicity studies carried out in this department, following the discovery of several naturally occurring nickel-toxic soils in Aberdeenshire, have established that 2.5 p.p.m. nickel (as sulphate) in the

nutrient solution will produce marked necrosis in oats grown in sand culture. The form of iron supplied (versenate or citrate) has no effect on the intensity of the toxic symptoms, although an increase in iron-level reduces necrosis³.

Soil studies had indicated that much of the nickel in a peaty nickel-toxic soil is present in chelate form, associated with the soil organic matter, and that this nickel is readily available to plants. It was therefore decided to investigate the effect of a chelate form of nickel on oats in sand culture.

Nickel versenate (1 mol. nickel to 1.5 mol. ethylenediamine tetra-acetic acid) was supplied at a level equivalent to 2.5 p.p.m. ionic nickel in the nutrient solution. Iron was given either as versenate or citrate at 1.2 p.p.m., and plants received nutrient solution in adequate amounts twice daily from germination.

Ionic nickel produced characteristic longitudinal white striping of the oat leaves, which first appeared when plants were 5 cm. high. The plants supplied with nickel versenate were still a healthy green when the experiment was sampled at the end of thirty-five days. Plants were dried and major elements, nickel and iron, determined in the dry matter after ashing. Variation in treatment produced no significant differences in content of major elements. Average values for yield and nickel and iron contents of the two pots in each treatment are set out in the accompanying table.

	Fresh yield per pot (gm.)	p.p.m. Metal in dry matter	
		Iron	Nickel
<i>Ferric citrate series</i>			
Control	65.5	100	11.3
2.5 p.p.m. Ni^{++}	56.5	104	12.4
2.5 p.p.m. Ni as versenate	73.9	91	9.7
<i>Iron versenate series</i>			
Control	67.6	107	8.4
2.5 p.p.m. Ni^{++}	57.7	105	100
2.5 p.p.m. Ni as versenate	64.7	91	14.5

Since the level of nickel in plants supplied with nickel versenate did not vary significantly from that of the controls, whereas in plants receiving ionic nickel at the same concentration the level was more than ten times as great, the inference is that no absorption of the nickel complex occurred. For the same reason, it would appear that the plants were unable to remove nickel from the complex at the root surface, although this may well have been the mechanism operative in the case of iron.

Rate of Milk Secretion in Dairy Cattle in the Intervals between Consecutive Milking

With dairy cows milked by the normal methods, a proportion of the milk is not removed from the secretory tissues of the udder. This residual milk may be up to 20 per cent of the milk and contain 50 per cent of the fat present in the udder at the start of milking¹. The amount left is proportional to the milk yield².

Early experiments designed to determine the rate of secretion of milk did not allow for variations in

the amount of this residual milk, and it was assumed that the yield of milk obtained at a milking was a true measure of the amount secreted since the last milking. These experiments^{3,4} indicated that the rate of secretion of milk and fat is inversely proportional to the time since the last milking, and that the rate of formation of the milk fat declines more quickly than the non-fatty fraction. The importance of residual milk in experiments on rate of secretion has been pointed out by Turner⁵, who, after correcting for these effects, suggests that rate of milk secretion does not decline for twenty hours after the last milking. Using an experimental method designed to eliminate residual milk effects, it has been shown at this Institute that the rate of formation of milk and fat both decline with increasing interval since the last milking, and the fall in the rate of secretion of fat is not greater than that of the milk.

Experimental method. In order to eliminate the effect of residual milk the following experimental method was adopted. Five cows were milked at intervals of 3, 6, 9, 12, 15 and 18 hr., the order of milking being as follows: 12 (6), 9 (5), 15 (5), 6 (8), 18 (5), 3 (24), 18 (6), 6 (10), 15 (8), 9 (7), and 12 (6). The figures in brackets indicate the number of consecutive milkings carried out for each interval. This method differed from that of the earlier workers in that five or more consecutive milkings were carried out for each of the milking intervals.

Results. The individual milk-yields in each series of milkings were similar, and it follows that the amounts of residual milk left after each milking in a series were also similar. Therefore, the milk obtained at each of these milkings can be regarded as the quantity secreted in the previous milking interval, provided that the initial milkings after each change-over are not considered.

Fig. 1 illustrates the average amount of milk secreted after the various intervals and the fat percentages of the milk calculated from the results for the five cows. In the case of the graph of fat percentage, the results are shown in two ways. Curve B is the graph obtained by using a mean of the consecu-

Fig. 1. The mean yield (A) and fat percentage (B) of the milk secreted by five cows in the first 18 hr. after the last milking; (C) shows the fat percentage of the milk obtained when no attempt is made to standardize the previous milking interval.

tive milkings disregarding at least the first two readings after change-over, and curve *C* is obtained when only the first reading after each change-over is used. The results used in the latter graph are those influenced by residual milk effects, and they have been calculated by a method which approximates to that used by earlier workers^{3,4}.

From curves *A* and *B* it will be seen that the true rate of secretion of both milk and fat declines with increasing interval since the last milking. The milk-yield result is in agreement with Ragsdale *et al.*³ and Johansson⁴, but not Turner⁵. Curve *B* illustrates that the rate of decline of the fat secretion is not greater than the decline in milk secretion. In fact, the reverse is probably true, because the mean fat percentages of the milk secreted in 3, 6, 9, 12, 15 and 18 hr. are 2.86, 3.02, 3.19, 3.17, 3.20 and 3.24 per cent respectively. The results illustrated by curve *C* are influenced by residual milk and show a similar trend to those of Ragsdale *et al.*³ and Johansson⁴.

Low Niacin Concentration in the Breast Milk of Bantu Mothers on a High-Maize Diet

GOLDSMITH and co-workers¹ prepared wheat and maize diets containing equal, though relatively small, amounts of niacin and tryptophan, 4.7 and 190 mgm. per diam respectively; when fed to human subjects, only those consuming the maize diet developed pellagra. In view of this abnormality of metabolism on the maize diet, it has been considered worth while to investigate whether a diet containing this cereal causes any abnormality in the concentrations of niacin and tryptophan in breast milk. Available information suggests that the level of niacin in the breast milk of White mothers is relatively independent of dietary intake². In South Africa, however, Kropman³ found twelve Bantu breast milks to contain an average of 108 μ gm. niacin per 100 ml.; this average is low in comparison with the mean value of 183 μ gm. obtained for the milks of 288 American mothers⁴. Kropman³, unfortunately, provided no dietary information on the mothers concerned—an important point in the present issue, since the consumption of maize by the Bantu varies enormously, one report giving a range of 6–20 oz. per diam for urban dwellers⁵.

To throw light on the subject, breast milks from four groups of mothers have been investigated: (1) Urban Bantu mothers in poor circumstances whose consumption of maize meal (90–100 per cent extraction) exceeded 1 lb. per diam, and supplied 65–85 per cent of total calories; (2) Indian and Eurafian mothers consuming a small though variable amount of maize; (3) Bantu and Indian mothers accustomed to an almost Europeanized diet;

(4) European mothers in comfortable circumstances who served as controls. Milk from groups 1–3 mothers were obtained, mainly from 10.30 a.m. to noon, when subjects were attending clinics for routine examination of their infants or themselves. All collections were 'spot' samples. Nevertheless, self-demand feeding is the rule among non-White mothers, that is, differences in composition between 'fore' and 'hind' milks are thereby minimized. Niacin was determined microbiologically by the method described by Gyorgy⁶. Tryptophan determinations were carried out—on milks from groups 1 and 4 mothers only—by the microbiological method of Greene and Black⁷. Estimations of intakes of niacin and tryptophan were calculated, using local⁸ and American⁹ food tables respectively, from dietary information collected by our dietitian, Miss J. L. Seward. These data, together with results of the determinations of these nutrients in the breast milks, are given in the table.

INTAKES AND BREAST MILK CONCENTRATIONS OF NIACIN AND TRYPTOPHAN OF BANTU AND OTHER MOTHERS

Group of mothers	Niacin		Tryptophan	
	Intake (mgm./diam)	Breast milk (μ gm./100 ml.)	Intake (mgm./diam)	Breast milk (μ gm./100 ml.)
1. Bantu (high-maize diet)	15–18	70 $\pm$ 51 (28)* (15–140)	550–850	23 $\pm$ 6 (18)* (11–33)
2. Indian and Eurafian	not estimated	105 $\pm$ 45 (15)* (60–175)	not estimated	not estimated
3. Bantu and Indian (Europeanized diet)	not estimated	150 $\pm$ 52 (8)* (83–270)	not estimated	not estimated
4. European	9.5–15	175 $\pm$ 48 (8)* (110–226)	1,100–1,400	21 $\pm$ 4.5 (12)* (13–29)

* Number of milks examined.

Digestion of group 1 breast milks with *N* sodium hydroxide for 10 min. at room temperature caused no increase in niacin concentration; hence, the vitamin is present wholly in 'unbound' or available form¹⁰. The difference between the means of the niacin concentrations in groups 3 and 4 mothers is not significant; in this respect, therefore, the racial factor is unimportant.

The salient observation is that, despite a probably higher intake of total niacin, the mean niacin concentration in breast milk of the high-maize Bantu mothers is much lower than the mean value for the combined groups 3 and 4 mothers consuming the European diet. The difference is statistically highly significant ($P < 0.001$). Calculation reveals the loss of niacin in the breast milk to be small in comparison with total niacin intake—approximately 5 per cent for group 1 mothers at the third month of lactation.

Considering the results as a whole: first, wide variations of niacin concentration occur within groups, as with other constituents¹¹; secondly, mean niacin concentrations increase with decreasing maize consumption. Obviously, it would be erroneous to interpret differences in niacin concentration in terms of maize intake only. However, it would seem reasonable to regard the unusually low concentration of the vitamin in Bantu breast milk as reflecting a further abnormality of niacin metabolism under conditions of high maize intake. Whether the abnormality is due to a large proportion of ingested niacin being 'bound', or to suppression of intestinal

biosynthesis of the vitamin, or to other causes, requires further investigation.

The low intake of niacin by Bantu breast-fed babies is not apparently deleterious, for local pediatricians aver that there is parity of growth and general health between Bantu and European babies when exclusively breast-fed up to six months.

There is no statistical difference between the mean concentrations of tryptophan in the breast milks of the Bantu and European mothers (groups 1 and 4).

The determinations of niacin and tryptophan were carried out by Mr. G. Smith and Miss H. S. P. Snyman, of the South African Bureau of Standards, Pretoria. This communication is published with the permission of the South African Council for Scientific and Industrial Research.

Formation of Enzymatically Active, Dialysable Fragments during Autodigestion of Pepsin

NORTHROP and co-workers have shown¹ that pepsin in solution digests itself with the formation of material soluble in trichloroacetic acid. The amount of non-protein substance formed depends upon factors such as time, temperature, and the pH and composition of the solvent. It has now been found in this laboratory that if autodigestion of pepsin proceeds at pH values removed from those optimal for proteolysis, pH 1.5-2.0, activity can be recovered in the non-protein fraction.

In a typical experiment, 0.6 gm. Worthington crystalline pepsin is dissolved in 60 ml. 0.1 M sodium acetate buffer of pH 5.6. The solution is then incubated at 37° C. and 10-ml. samples are withdrawn at intervals of 12, 18, 24, 30, 36 and 48 hr. and quickly chilled to 5° C. A portion of each sample is next dialysed at the low temperature for 24 hr., against 2.5 volumes of the acetate buffer. With the aid of the haemoglobin method², the activities of the protein, both before and after dialysis, and of the dialysate are determined. Enzymatically active fragments are found in the dialysate after incubation at 37° C. for 24-48 hr. This material represents 10-20 per cent of the total protein and has an activity, per unit of nitrogen, of 1-5 per cent relative to that of the intact enzyme. The dialysable material is inactivated on heating to 100° C. for five minutes or on prolonged incubation at 37° C. After passage of the hydrolysate through a column of 4 per cent cross-linked 'Dowex 50', at

Pepsin	9	1.33	95	not tested
Pepsin, dialysed		1.28	110	not tested
Dialysate		0.1†	0	0
Pepsin	48	1.34	97	95
Pepsin, dialysed		1.16	93	100
Dialysate		0.2†	8	64

* The relative specific activity of a freshly prepared dialysed enzyme solution is taken as 100.

† Nitrogen values of the dialysate refer to 1 ml. of the original protein solution.

least two active components are isolated from the eluate. Similar results have been obtained with five crystalline preparations of pepsin, although the amount of active dialysable material found on incubation varies somewhat with the length of storage of the crystalline enzyme. In all these experiments, tests for bacterial contamination were made in order to eliminate this as a source of activity.

Although, as indicated with a typical experiment listed in Table 1, the activity of the dialysable fraction against haemoglobin is low, that against the synthetic substrate acetyl-L-phenylalanyldiiodotyrosine³ is 64 per cent of the value for the intact protein. It thus seems reasonable to suppose that the active fragments may represent a portion of the original protein with an amino-acid configuration specific for the hydrolysis of a peptide bond adjacent to a tyrosine residue⁴. In contrast, the low activity against the protein substrate may be taken as an indication that proteolysis of haemoglobin involves a variety of types of bonds, for some of which the dialysable fragment has a reduced activity.

I wish to thank Dr. Lillian E. Baker for a generous sample of acetyl-L-phenylalanyldiiodotyrosine and Dr. Lewis G. Longworth for suggestions during preparation of the manuscript.

Effect of Temperature on Leaf-shape in *Ranunculus*

In trifoliate species of *Ranunculus* the first-formed and juvenile leaves are undivided, and as the plants mature the adult trifoliate or biternate condition is gradually taken up by new leaves. Quite frequently, however, some of the later leaves of mature plants show a partial reversion to a less divided, more juvenile form. This reversion may occur in leaves of similar age in many plants in a single area, which suggests a temporary or seasonal environmental cause.

An investigation has recently been carried out to determine the separate effects upon leaf-dissection

of differences in humidity, light-intensity and temperature. Using a pair of controlled-environment cabinets¹ it has been possible to grow plants for extended periods varying only one of the three major environmental factors at a time. Batches of twenty-seven adult plants of *Ranunculus hirtus* B. and S., a trifoliate species of forests in Australia and New Zealand, were grown for three months under each set of conditions. Illumination throughout was provided by Philips warm-white fluorescent tubes with a fourteen-hour day. The conditions that were applied are shown in the accompanying table.

Batch	Humidity (rel. per cent)	Light intensity (foot-candles)	Temp. (° C.) Day Night
1 A	95-98	{400}	{15 10}
B	45-50		
2 A	{90-94}	200	{15 10}
B		800	
3 A	{90-94}	{400 day}	{10 5}
B			

Although marked differences in size, habit and root-shoot ratio developed between the A and B batches of the first two experiments, no differences in leaf-dissection were produced. In the third experiment, however, marked differences in leaf-dissection were produced under different temperatures. Under the higher temperature there was a complete reversion to an undivided juvenile leaf-form in all leaves opening after six weeks from the start of the experiment. Under the cooler conditions the leaves kept their adult trifoliate form.

The reversion effect produced by the higher temperature persisted in new leaves for a further two months after the plants were replaced in the open at the end of the experiment. Subsequent leaves reverted to the original adult state.

This investigation has been carried out with the assistance of a Biological Research Grant and maintenance allowance from the Nuffield Foundation. A full account of this work will be published elsewhere.

Anatomy of Roots and Shoots of *Brassica campestris* L. in Relation to Vernalization

The present communication summarizes the results of a further study¹ of the comparative anatomy of plants raised from vernalized and normal seeds of mustard. The technique used for radicles, shoot apices and stems fifteen days old has been described elsewhere^{1,2}. Stems at the ages of 37, 45 and 56 days, using the method of Wilton and Roberts³, were fixed in formalin-aceto-alcohol, passed through the *n*-butanol series, embedded in paraffin, sectioned 15-18 μ thick and stained with erythrosin and crystal violet.

Radicle. The structure of the normal radicle and its vascular differentiation have already been described⁴. The following table presents a comparative study which shows that there is earlier initiation of differentiation of vascular elements in vernalized radicles.

Shoot apices. A search for differentiated protoxylem elements in the median traces of the various leaves on the shoot apices of plants 15 days old showed

Nature of seeds	Treatment	Condition of vascular elements at each pole	
		Protophloem	Protoxylem
Unsplit	Normal	No differentiation	No differentiation
"	Vernalized	One differentiated element	One differentiated element
Just split	Normal	"	One at various stages of differentiation
"	Vernalized	1-2 differentiated elements	2-3 differentiated elements

that in all the five plants obtained from treated seeds, the median trace of the fourth leaf from the apex has either a mature, an immature, or both types of xylem elements, while in the corresponding controls only two plants out of seven show this feature. Thus, in vernalized plants comparatively younger leaves have xylem elements differentiated first.

In the 15-day old sample, out of eight vernalized and seven control shoots examined, six apices of the former possess three layers of tunica and only two of the latter. Thus, the advanced stage of development marked by three-layered condition of the tunica⁵ is reached earlier in the vernalized material. A week later the apices of the treated plants have all the characteristics of a reproductive shoot⁶, whereas those of the untreated plants possess a three-layered tunica, the cells of which are approaching a columnar condition.

Stem. In the case of 15-day old material, scarcely any difference could be observed between the treated and normal ones, and there is vigorous cambial activity in both which starts in seedlings three to four days old. In the second sample (37 days old), the vernalized plants possess a pericycle zone the cells of which could be distinguished from the cortical ones whereas in the control plants they could not. The former also possess thicker-walled medullary ray cells and comparatively smaller vessel elements in the xylem, which is formed last.

In the sample collected at an age of forty-five days, besides the above-mentioned conditions, there is a greater thickening of the walls of the cells in the perimedullary zone of the vernalized plants. The cells in the bundle caps, medullary rays and perimedullary zone of the treated plants fifty-six days old are thicker-walled and they stain with crystal violet, as opposed to those of normal stems (Figs. 1 and 2). Again, the walls of the phloem cells in the vernalized plants are slightly thickened and more compressed, and there are few vessels in the latest formed xylem.

Thimann⁷ suggested that early flowering might result from the differences in the supply system and,

Figs. 1 and 2. Transverse section, second elongated internode below the terminal inflorescence of 56-day old control and vernalized plants of mustard, respectively. Arrow indicates bundle cap. $\times 100$

therefore, in the materials made available to the developing initials. Earlier differentiation of the vascular elements in vernalized mustard indicates that this is a possibility. A direct relationship between the flowering impulse and the activity of the cambium has been recorded by several workers¹. Struckmeyer² even observed a decrease in the activity of the cambium in plants within a short period of their subjection to photoperiods suitable for flowering. In the present case, however, no such abrupt change could be detected, and all the treated plants possessed a normally developed cambium, indicating thereby that the substance or substances formed during chilling are not direct flower-forming substances and thus differ from those synthesized in the leaves³ during photoperiodic treatment. Similar conclusions have also been arrived at by several workers with cereals⁴, although the substance or substances formed in mustard seeds during chilling differ from those in cereals in certain respects¹.

A detailed account of the comparative anatomy of mustard and several other plants will appear in the *Indian Journal of Agricultural Science*.

Long-Term Adaptation to the Fermentation of Galactose in *Saccharomyces chevalieri*

THE dominant gene, controlling the adaptive fermentation of galactose, and the recessive gene, carried by the Carbondale stocks of *Saccharomyces* incapable of fermenting galactose, comprise a pair of extraordinarily stable and well-defined alleles. The non-fermenters of the Carbondale stock contain no detectable galactozymase and are incapable of fermenting galactose. Exceptional cultures called 'long-term' fermenters of galactose ferment galactose on duplicate tests after irregular periods of 4-30 days, while the corresponding stocks carrying the dominant allele cause fermentation within 48 hours. Mundkur and Lindgren¹ mated rapid-fermenter mutants isolated from 'long-term' fermenters with non-fermenters and found that the capacity for rapid fermentation segregated regularly at reduction, thus establishing the genic nature of the adaptation and the basis for the view that in the long-term fermenter a change occurs from non-fermenter to fermenter. The rapid fermentative character was retained by the original mutant and the segregant offspring after serial transfer on glucose.

Saccharomyces chevalieri is a 'long-term' fermenter different from the long-term fermenters of the Carbondale stock. Winge and Roberts² showed (1) that fermentation occurs regularly after a delay of 4-8 days, (2) that the adapted cultures ferment galactose rapidly, and (3) that most of them lose their ability to ferment galactose rapidly, that is, become 'de-adapted' after growth on glucose or maltose. They proposed that adaptation and de-adaptation involved

the entire population. Spiegelman, De Lorenzo and Campbell³ showed that the capacity for rapid fermentation is distributed discontinuously among the members of the rapidly fermenting culture. Mundkur⁴ found that matings between the rapid fermenters isolated from *S. chevalieri* and non-fermenter cultures of the Carbondale stocks produced hybrids in which the character for rapid fermentation segregated at reduction, proving that the change from non-fermenter to fermenter in *S. chevalieri* occurred as the result of mutation and selection of the mutant in the presence of galactose. He also indicated that the gene controlling rapid fermentation undergoes reverse mutation.

Nearly all *Saccharomyces* cultures produce variable numbers (1-10 per cent) of small smooth colonies which stand out in sharp contrast to the normal larger colonies on an agar plate. It was shown by Lindgren and Lindgren⁵ that most of the extensive morphological variation characteristic of *Saccharomyces* haploids arises from the small smooth colonies. Ephrussi⁶ found that the numbers of small smooth (petite) colonies can be increased by exposure to acriflavine and that both the spontaneous and the induced petites are deficient in cytochrome. *S. chevalieri* resembles other *Saccharomyces* in producing petite colonies which do not consume oxygen or utilize lactate⁷. Direct observation of budding has revealed that mitochondria are distributed to the bud at random and that some buds may receive only a single mitochondrion⁸, thus supplying the possible mechanism for the loss of cytochrome and the origin of petites. When petite colonies of *S. chevalieri* are plated on eosin-methylene blue galactose-agar containing peptone and yeast extract, the discontinuous nature of the transformation from non-fermenter to fermenter of galactose can be observed. By the seventh day nearly two-thirds of the colonies contain one or more red papillae. Subcultures isolated from the red papillae ferment galactose rapidly (within two days) and do not become de-adapted after serial transfer on glucose. These rapid fermenters of galactose retain the characteristic small size of petites and are respiratory-deficient, being unable to consume oxygen with either glucose or galactose as the substrate. The large colonies also produce normal papillae on *EMB* agar which overgrew the colonies by the fifth and sixth days. On the basis of Mundkur's findings⁴, it seems obvious that the discontinuous origin of the stable fermenters is by gene mutation.

Deliberate mixtures of the petite fermenter and the normal unadapted type were grown in glucose broth and on glucose-agar plates. In both cases the respiratory-sufficient normal strain overgrew the petite fermenter and the culture became 'de-adapted' to a long-term fermenter. Small numbers of stable rapid fermenters of the normal type in deliberate mixtures are inhibited by the presence of the normal unadapted strain when the two are planted in defined galactose agar. This phenomenon explains certain discrepancies encountered in fluctuation tests and validates the variance method in yeast genetics. It is inferred (1) that fermentation of galactose by *S. chevalieri* is due in part to mutation of a gene controlling galactose fermentation, and (2) that the fermenting culture is a mixture in which (3) de-adaptation is achieved by reversion to the non-fermenter type on transfer to glucose. The evidence presented above shows that a major mechanism in 'long-term' adaptation is mutation and selection, complicated by suppression; but, specific

DIFFERENTIAL BEHAVIOUR OF *Saccharomyces diastaticus* AND ITS
PETITE VARIANT IN ADAPTATION TO GALACTOSE

Classification of colonies	Respiratory activity of cells	Adaptation to galactose in fermentation tubes (defined medium)	Formenter papillae on colonies grown on MMS complete galactose agar	Characteristics of rapid fermenters of galactose
Normal (large)	Respiratory-sufficient; utilize lactate; consume oxygen	Fermentation completed in all tubes in 5-7 days	100 per cent of colonies contain one or more papillae by 3rd or 4th day; overgrown by 5th and 6th days	Normal (large colonies) respiratory-sufficient, rapid (two-day) fermenters of galactose; may become de-adapted
Petite (small)	Respiratory-deficient; cannot utilize lactate; do not consume oxygen	Fermentation irregular; completed in 9-18 days	Less than 1 per cent of the colonies contain papillae by 3rd or 4th day; 64 per cent of colonies contain one or more papillae on 7th day	Small colonies, respiratory-deficient, rapid (two-day) fermenters of galactose; do not become de-adapted

experiments were not devised which would exclude the possibility that mechanisms involving cytoplasmic particles or slow genes may co-exist. Most of the normal rapid fermenters of galactose yield de-adapted populations after growth on a galactose-free substrate. Some of the petite rapid fermenters derived from the de-adaptable respiratory-sufficient fermenters also become de-adapted. These data are consistent with the views that an extra chromosomal apparatus may be involved^{2,3}; the possibility that two mechanisms may operate simultaneously in adapting populations warrants serious consideration in formulating a concept of microbial adaptation.

Identification of the Genes for Maltose Fermentation in *Saccharomyces diastaticus*

Winge and Roberts¹ have established that *Saccharomyces cerevisiae* contains three polymeric genes for maltose fermentation, M_1 , M_2 , and M_3 , and they have obtained by mutation a fourth maltase gene (M_4).

It has been found² that *Saccharomyces diastaticus* contains two maltase genes, one governing normal fast fermentation (M_F) and one governing slow or delayed fermentation of maltose (M_S).

Prof. Ø. Winge has very kindly made available four hybrid yeasts each of which is homozygous for one of the genes M_1 , M_2 , M_3 , or M_4 . These yeasts were crossed, by Winge's spore-to-spore method, with cultures which were homozygous for M_F or M_S alone. Four-spored asci of the hybrids thus obtained were analysed for the segregation of maltose fermentation with the results shown in the accompanying table.

Crossing	Number of 4-spored ascus of the hybrid giving segregation of maltose fermentation 4+ : 0- 3+ : 1- 2+ : 2-			Probability of this distribution if the two genes are non-allelic allelic	
$M_F \times M_1$	6	0	0	0.0003	1
$M_F \times M_2$	2	2	1	0.06	0
$M_F \times M_3$	0	5	1	0.13	0
$M_F \times M_4$	1	4	1	0.16	0
$M_S \times M_1$	0	5	1	0.13	0
$M_S \times M_2$	0	6	0	0.09	0
$M_S \times M_3$	2	3	1	0.06	0
$M_S \times M_4$	1	3	2	0.08	0
Theoretical 2-gene segregation	1	4	1		

It is thus established that the M_F gene of *S. diastaticus* is M_1 . It is also established that the M_S gene of *S. diastaticus* does not correspond with any of the four genes M_1 , M_2 , M_3 , or M_4 , and it may be called M_5 .

The maltase gene in *Saccharomyces italicus* was also identified³ as M_1 , so that this gene is common to all the naturally occurring maltose-fermenting yeasts so far examined.

Environmental Influences and the Maxillary Index in *Anopheles gambiae*

APPARENTLY contradictory reports of the behaviour of *Anopheles gambiae* in different parts of Africa have led to suggestions that more than one biological race of this species exists. In French West Africa, Holstein¹ has attempted to correlate these differences with variation in the maxillary index—the number of teeth on both maxillae, divided by two. He has recognized a pseudidentate population with a maxillary index of 13.5 and a multidentate population with an index of 15. The former is said to be anthropophilic, mainly exophilic and to breed for preference in temporary pools in which the organic content of the water is low; the latter to be zoophilic, endophilic and to breed in permanent types of water of high organic content. Holstein has stated unequivocally that these two populations represent distinct biological races, and in this he has been supported by

Campbell², working in Gambia, who was able to confirm the difference in maxillary counts in females emerging from different breeding sites.

These conclusions are of considerable epidemiological and practical importance; but up to now it seems that critical attention has not been paid to the possibility that some of this morphological variation might be due to environmental influences. To explore this possibility the following experiment was carried out.

Individual egg batches were obtained from wild-caught *A. gambiae* from Muheza in Tanganyika. Each batch was divided into two parts, which were reared separately, with the object of finding a combination of breeding conditions that might have a maximum effect on the maxilla. One part was reared at a thermostatically controlled temperature of 32.2° C., the other at room temperature, which fluctuated around a mean of 21.1°. As it was found that overcrowding influenced both the maxillary counts and wing-length, an average of 100–150 eggs was put into the hot bowls, and, with the exception of the first experiment, 300–450 into the cool bowls. Thus 400–600 eggs were used in each experiment, the number of eggs taken from each batch depending on the number of batches available. Eggs were transferred to the appropriate bowls (12 in. × 10 in.) some 12–36 hr. after deposition; pupae were reared in separate containers but at the same temperature as their respective larvae. All larvae were fed on a suspension of a commercial preparation of yeast ('Perolin'). Little difficulty was encountered with feeding, although there was a considerable mortality among the later instar larvae in the crowded bowls.

The results of six experiments on these two genetically identical groups, shown in Table 1, gave striking evidence of the wide variation in maxillary index that could be induced by simple alteration of the larval environment. It appeared also that growth of the maxillae was not obviously related to linear growth as measured by wing-length (parents, 2.9 ± 0.06 mm.; hot bowls, 2.72 ± 0.06 mm.; cool bowls, 3.12 ± 0.06 mm.).

15–5 days

This work makes it clear that, unless adults are reared under standard conditions, no valid comparisons can be made of the maxillary indices of populations derived from different localities or breeding sites. On these grounds, the conclusion of Holstein and Campbell, that the differences between the two populations of *A. gambiae* that they studied were genetically determined, cannot be accepted as it stands; nor can the possibility be ruled out that much of this variation was phenotypical.

While differences of a geographical nature may, and probably do, exist, it must be concluded that there is no convincing evidence available at present

that points to the co-existence in the same region of biological races of this species.

Failure to Publish Scientific Results

I wish to direct attention to the large amount of scientific work carried out at the public expense but only reported in brief summary terms or published after long delay. This may be due in part to habits acquired in war-time, when the scientist was too busy to prepare papers for publication and the journals so restricted that they could not accept them. It is due also to the dangerous custom of writing a number of progress reports which are circulated within groups of Government committees in stencil: the authors frequently do not face the labour of preparing a paper of the type which a conscientious editor would accept.

It seems that an example is furnished by some of the work carried out under the Colonial Research Council*. Under that Council is a committee dealing with insecticides which met first in January 1947. Since the report for 1948–49, that Committee has referred each year to experiments being done with insecticidal sprays from the air in East Africa. It is evident from the page or so published that the investigation is well staffed (indeed in the last year the staff consisted of "4 entomologists, a physiologist, a chemist, a senior executive officer and 9 European assistants"); it also appears to be well planned: one notes that there is a careful estimation both of the insecticide that reaches the ground and of the insect populations which are the target. The group of workers carrying this out appear to have published no scientific papers until the end of 1953^{1,2}. These papers apparently deal with experiments carried out so long ago as March 1948.

It seems probable that the work done by this group in East Africa is more full and careful than that performed by any other country; but if one wishes to know about insect destruction by aerial spray, one must use the other people's work because it is available.

This British work on insecticides is lavishly financed and has received 7.5 per cent of the £12,000,000 allocated to the Colonial Research Council up to 1953, namely, £900,000. As most of the work carried out by the Insecticide Committee appears not to be very expensive, we conclude that the air spraying has cost about three-quarters of a million pounds. It is difficult to see why work should be done and paid for, if it is not made available or if it is to be published after it is out of date.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, March 1

ROYAL SOCIETY OF EDINBURGH (at 24 George Street, Edinburgh), at 4.30 p.m.—Prof. James Kendall, F.R.S.: "Humphry Davy and his Connections with Scotland".

SOCIETY OF ENGINEERS (in the Apartments of the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. C. R. Young: "Progress in Petroleum Refining".

UNIVERSITY OF LONDON (in the Physics Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. R. B. Marshak (Rochester, U.S.A.): "Scattering of Mesons by Nucleons". March 3: "Nucleon-Nucleon Scattering at High Energies". March 5: "New Unstable Particles".

UNIVERSITY OF LONDON (in the Chemistry Lecture Theatre, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7), at 5.30 p.m.—Prof. O. W. Fige, F.R.S. (Moulbourne): "The Flight Muscles of Insects". (Further Lectures on March 2 and 3.)

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE, PHILOSOPHY OF SCIENCE GROUP (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.45 p.m.—Annual General Meeting.

Tuesday, March 2

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. A. J. Arkell: "Pebble and his Mycological Collection".

INSTITUTE OF CHEMICAL ENGINEERS (in the Apartments of the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. H. Hoog: "The Importance of Chemical Engineering Studies in Relation to Process Development".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 6 p.m.—Sir Lawrence Bragg, F.R.S.: "X-Ray Optics". (Further Lectures on March 9 and 16.)

ROYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. F. Tyson: "Metal Sandwich Construction".

SOCIETY FOR VISITING SCIENTISTS LTD. (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion on "The Science of Clothing".

Wednesday, March 3

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. G. P. Whibberley: "The Challenge of Rural Land Losses".

SOCIETY FOR ANALYTICAL CHEMISTRY (in the Meeting Room of the Royal Society, Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Annual General Meeting; Dr. N. B. Hughes: "The Contribution of Public Analysts and Other Analytical Chemists to Public Welfare" (Bernard Dyer Memorial Lecture).

Thursday, March 4

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 3 p.m.—Dr. Irving P. Krick: "Weather Modification and its Value to Agriculture and Water Supply".

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. A. A. Hall, F.R.S.: "The Work of the Royal Aircraft Establishment".

BRITISH POSTGRADUATE MEDICAL FEDERATION (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Prof. G. M. Bull: "Regulation of Body Water". (Last of fifteen lectures on "The Scientific Basis of Medicine".)

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 6 p.m.—Sir Harold Spencer Jones, F.R.S.: "Changes in the Rotation of the Earth". (Further lectures on March 11 and 18.)

INSTITUTE OF METALS, LONDON LOCAL SECTION (at 4 Grosvenor Gardens, London, S.W.1), at 6.30 p.m.—Dr. J. P. Dennison: "High Temperature Corrosion".

ROYAL AERONAUTICAL SOCIETY (at the Royal Fort Physics Laboratory, Bristol), at 7 p.m.—Major G. P. Bulman, O.B.E.: First Barnwell Memorial Lecture.

UNIVERSITY OF LONDON (at Wye College, Near Ashford, Kent), at 8.15 p.m.—Prof. P. B. Medawar: "Some Problems of Individuality in Cattle, Mice and Men".

Friday, March 5

SOCIETY OF CHEMICAL INDUSTRY (joint meeting of the COMBUSTION GROUP and the GLASGOW SECTION, in the Royal Technical College, George Street, Glasgow), at 2.30 p.m. and 7.15 p.m.—Scientific Papers.

SOCIETY OF COSMETIC CHEMISTS OF GREAT BRITAIN (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 7 p.m.—Mr. J. Pickthall: "Talking of Perfumes".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. H. Munro Fox, F.R.S.: "Oxygen and Life".

Saturday, March 6

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 2.30 p.m.—Mr. Norman Cook: "Roman London".

BRITISH INTERPLANETARY SOCIETY (in the York Hall, Caxton Hall, Westminster, London, S.W.1), at 6 p.m.—Mr. N. B. Nicoll: "The Design of a Life Compartment Necessary for Space Travel".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER IN PHYSICS, and an ASSISTANT LECTURER IN THEORETICAL PHYSICS—The Registrar, King's College, Strand, London, W.C.2 (March 6).

PRINCIPAL OF BRITISH TECHNICAL COLLEGE—The Clerk to the Governors, 11 Essex Road, Dartford, Kent (March 6).

RESEARCH ASSISTANTS (8) (graduates, preferably in economics, agricultural economics, agriculture or geography) IN THE DEPARTMENT OF AGRICULTURAL ECONOMICS—The Registrar, Wye College, near Ashford, Kent (March 6).

SCIENTIFIC OFFICER (with first- or second-class honours degree in chemistry, geology or geography) IN THE DEPARTMENT OF PEDOLOGY, Soil Survey (Scotland) Section—The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (March 6).

HOSPITAL PHYSICIAN (basic grade) IN THE PHYSIC DEPARTMENT—The Secretary, Board of Governors, Hammesmith Hospital and Postgraduate Medical School, Du Cane Road, London, W.12 (March 9).

ASSISTANT LECTURERS (with special qualifications in physical chemistry, and for one post preferably with experience in surface chemistry) IN CHEMISTRY—The Registrar, The University, Manchester (March 12).

PARASITOLOGIST (with a degree in veterinary science, agricultural science or zoology) IN THE DEPARTMENT OF AGRICULTURE—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting Ref. No. 8/432 (March 13).

SENIOR PHYSICIST (with honours degree and at least five years experience in hospital physics or related research, and preferably with a practical knowledge of radio-elements)—The Group Secretary, Northern Group Hospital Management Committee, Royal Northern Hospital, Holloway, London, N.7 (March 13).

STAFF TUTOR IN SCIENCE (Physics or Chemistry) IN THE DEPARTMENT OF ADULT EDUCATION, to conduct University Tutorial or Seasonal Classes, to advise part-time tutors and to foster and organise the demand for scientific studies—The Registrar and Secretary, The University, Bristol 8 (March 13).

BIOLOGIST (with a university degree or equivalent qualification and some experience in freshwater biology)—The Borough Engineer and Surveyor, The Council House, Derby (March 15).

DEMONSTRATOR (graduate, with qualifications or special interest in either mineralogy and petrology or palaeontology and stratigraphy) IN GEOLOGY—The Professor of Geology, University College, Keele, Staffs (March 15).

J. H. ANDREW RESEARCH FELLOW (with some research experience) IN THE DEPARTMENT OF METALLURGY—The Registrar, The University, Sheffield (March 15).

LECTURER IN INORGANIC CHEMISTRY—The Registrar, Queen Mary College, Mile End Road, London, N.1 (March 15).

SENIOR LECTURER or LECTURER IN BIOLOGY, LECTURERS IN CHEMISTRY, PHYSICS, ZOOLOGY and MATHEMATICS, at the Nigerian College of Technology—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (March 15).

ASSISTANT CURATOR at the Coryndon Memorial Museum, Nairobi, Kenya—The Curator, Coryndon Museum, Box 568, Nairobi (March 20).

PRINCIPAL RESEARCH OFFICER or SENIOR RESEARCH OFFICER (with university honours degree in science, including advanced training in chemistry and botany, and preferably with research experience in the field of cell anatomy or cell physiology of plants) in the Commonwealth Scientific and Industrial Research Organisation, Commonwealth Research Station, Merbein, Victoria, to investigate the dipping, drying and processing of vine fruits, including studies of the chemical, physical and physiological processes involved—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 490/40 (March 20).

LECTURER IN ELECTRICAL ENGINEERING—The Registrar, The University, Manchester 13 (March 22).

DAIRY OFFICER (with a degree in dairying, or an equivalent university degree with dairying qualifications) in the Department of Agriculture, Southern Rhodesia Government—The Secretary, Rhodesia House, 429 Strand, London, W.C.2 (March 25).

SENIOR RESEARCH OFFICER or PRINCIPAL RESEARCH OFFICER (with university honours degree and special training and research experience in fuel technology or in applied chemistry, or equivalent qualifications) IN THE COAL RESEARCH SECTION, Commonwealth Scientific and Industrial Research Organisation, North Ryde, New South Wales, Australia, in connexion with a comprehensive survey of the chemical and physical properties of Australian coals, to be responsible for the Section's work dealing with either (a) the carbonisation of coals, and to undertake investigations, including pilot scale studies, of their coke and gas making properties, or (b) the cleaning and preparation of coals, and to undertake investigations into their drying, screening and washability characteristics—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting A.490/107 (March 29).

DIRECTOR (with high qualifications in one of the sciences bearing on animal health, and considerable research and administrative experience) OF MORRUM INSTITUTE—The Secretary, Animal Diseases Research Association, Morrum Institute, Gilmerton, Edinburgh (March 31).

I.O.L. RESEARCH FELLOWSHIPS IN BIOCHEMISTRY, CHEMISTRY, CHEMOTHERAPY, ENGINEERING, METALLURGY, PHARMACOLOGY, PHYSICS or allied subjects—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 31).

LECTURER IN STATISTICS IN THE DEPARTMENT OF MATHEMATICS, University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Cape Town, March 31).

LECTURER or ASSISTANT LECTURER IN THE DEPARTMENT OF BOTANY—The Secretary, University College London, Gower Street, London, W.C.1 (March 31).

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

READER, SENIOR LECTURER or LECTURER (with special qualification in theoretical chemistry) in the DEPARTMENT of CHEMISTRY—The Registrar, The University, Manchester 13 (March 31).

TURNER and NEWALL RESEARCH FELLOWSHIPS in ENGINEERING, INORGANIC CHEMISTRY, PHYSICS or allied subjects—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 31).

RESEARCH FELLOW in the DEPARTMENT of MATHEMATICAL PHYSICS—The Registrar, The University, Birmingham 15 (April 20).

LECTURER in BIOCHEMISTRY—The Secretary, Queen's University, Belfast (April 30).

UNIVERSITY LECTURERS or UNIVERSITY DEMONSTRATORS in the FACULTY of ENGINEERING, University of Cambridge, to teach primarily in either the theory and use of materials, structural engineering or mechanical engineering—The Secretary, Appointments Committee, Engineering Laboratory, Cambridge (April 30).

JUNIOR RESEARCH FELLOWSHIPS in ORGANIC CHEMISTRY—The Secretary, Burbeck College, Malet Street, London W.C.1 (May 1).

RESEARCH FELLOWSHIP tenable in the DEPARTMENT of CHEMISTRY, University of Durham, for the study of nuclear reactions by radiochemical and micro gas-analytical methods—The Secretary, 38 North Bailey, Durham (May 1).

ROYAL DUTCH SHELL STUDENT (honours graduate in physics or geology, with mathematics and physics at intermediate level) in GEOPHYSICS—The Registrar, Imperial College of Science and Technology, London, S.W.7 (June 1).

ASSISTANT BACTERIOLOGIST (male) in the VACCINE LYMPH DEPARTMENT—The Bacteriologist-in-Charge, Lister Institute of Preventive Medicine, Herts.

ASSISTANT, Principal Scientific Officer grade (with first- or second-class honours degree in biology of a U.K. or Commonwealth University, or equivalent qualification), to the OFFICER in CHARGE, COLONIAL INSECTICIDES RESEARCH, for duties which will include the supervision of research work being undertaken under the aegis of the Colonial Insecticides, Fungicides and Herbicides Committee, and particularly the work of the Colonial Insecticides Research Unit in East Africa—The Under-Secretary of State, Research Department (S.610), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

BIOCHEMIST (with at least a B.Sc. honours degree, with three years postgraduate experience) in the East African Tsetse and Trypanosomiasis Research and Reclamation Organization, for duties which will include research on animal and insect physiology in connection with trypanosomiasis investigations in East Africa, routine biochemical tests, and to assist with biochemical problems in trypanosomiasis—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting ODH.77/88/OS.

CHEMIST, Scientific Officer grade, and a MYCOLOGIST, Scientific Officer grade—The Secretary, Ouseburn Experimental Station, Cheahunt, Herts.

ELECTRICAL or MECHANICAL ENGINEER (with first- or second-class honours degree or equivalent in electrical or mechanical engineering) at a Ministry of Supply Design Establishment, near Stevenage, Kent, for design and development of hydraulic and electrical equipment for A.A. mountings—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting O.113/64A.

ENTOMOLOGIST (with at least a good second-class honours degree, and with two years appropriate postgraduate experience) to investigate caterpillars and other insect pests of cacao and measures for their control; and an INSECTICIDE CHEMIST (with at least a good second-class honours degree, and with two years appropriate postgraduate experience) to test insecticides and methods for their application to cacao, including the design or improvement of machinery for this purpose, at the West African Cacao Research Institute, Gold Coast—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting ODH.87/11010-015.

GRADUATE PHYSICIST or FUEL TECHNOLOGIST (with ability to apply mathematics to heat transfer problems particularly concerned with the open hearth furnace) in the STEEL MAKING DIVISION, Sheffield—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "Steel-making".

HOSPITAL PHYSICIST, Senior grade (with first- or second-class honours degree)—The Secretary, Liverpool Radium Institute, 1 Myrtle Street, Liverpool 7.

LIBRARIAN (with a pass degree in science subjects or a library qualification, coupled with experience in a technical library), and an ASSISTANT LIBRARIAN (with H.S.C. or equivalent in science subjects, and some technical library experience), in the Technical Library—Administrative Officer (Recruitment), Department of Atomic Energy, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting 17/WGH.

MASTER to TEACH MATHEMATICS up to University Scholarship standard, and a MASTER to TEACH SCIENCE—The Headmaster, The King's School, Peterborough.

PHYSICIST (with first- or second-class honours degree and some research experience) for (a) fundamental research on the diffusion of ions in the protein keratin, and related substances, using radio tracer methods, and (b) for investigation of the mechanics of fibre movement using electronic and radioactive techniques—The Wool Industries Research Association, Torrington, Headingley, Leeds, 6.

PHYSICISTS (with a good honours degree, and some experience or training in research, not necessarily in textile research) to work on textile problems—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, near Manchester.

SENIOR SCIENTIFIC OFFICERS (with first- or second-class honours degree in botany or agriculture or a pass degree in agriculture, and at least three years postgraduate or other approved service, and a knowledge of the economic aspects of crops, and wide agricultural experience abroad, and preferably with specialized knowledge of local conditions in the Colonies) at the ROYAL BOTANIC GARDENS, Kew—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting B.4280/34.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF CIVIL ENGINEERING BURSARIES IN CONCRETE TECHNOLOGY

Notice is hereby given that the election to bursaries in Concrete Technology, tenable as from October, 1954, will take place in June, 1954. Candidates must hold a degree in engineering at the time of taking up the award, and must also have a good knowledge of the theory of structures. Bursaries are of the value of £350 per annum, out of which the College tuition fee has to be paid; the amount may be increased to £450 for those with industrial experience. In addition, one or two Senior Bursaries of £600 per annum may be awarded to outstanding men with a minimum of three years' experience in industry. The course will be postgraduate and Bursars who successfully complete the course will be eligible for award of the Diploma of the Imperial College (D.I.C.).

Applications must be received on or before June 1, 1954, by the Deputy Registrar, City & Guilds College, Exhibition Road, London, S.W.7, who will, on written request, send full information and application forms.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

ENGLISH ELECTRIC COMPANY'S BURSARIES IN HYDRO-POWER ENGINEERING

Notice is hereby given that a number of English Electric Company Bursars in Hydro-Power Engineering will be elected in June, 1954. The Bursaries are of the value of £250 for one year, tenable for graduate study in the Civil Engineering Department of the Imperial College. Bursars pay appropriate College tuition fee. The Bursaries are recommended for supplementation by the Ministry of Education. Bursars who successfully complete the course will be eligible for the award of the Diploma of the Imperial College (D.I.C.). Candidates should have an honours degree in engineering or an equivalent qualification.

Applications should be received before June 1, 1954, by the Deputy Registrar, City & Guilds College, Exhibition Road, London, S.W.7, from whom further details may be obtained.

SALTERS' INSTITUTE OF INDUSTRIAL CHEMISTRY

FELLOWSHIPS

Applications are invited for a Salters' Fellowship, value £600 per annum (plus university fees, and with F.S.S.U. benefit), for a graduate with an honours degree in chemistry, biochemistry, physics or engineering, in order that the appointed Fellow may obtain special training in industrial chemistry and contribute to the improvement of processes and products of industry by research in the field of the chemical sciences (including chemical engineering). The Fellowship will be tenable for one year from September 1, 1954, and renewable for one further year.

Applications should be received by the Clerk of the Salters' Company, 36 Portland Place, London, W.1, by March 31, 1954. Forms of application may be had on request.

INSTITUTION OF ELECTRICAL ENGINEERS

SCHOLARSHIPS

The Council of The Institution of Electrical Engineers will consider for award this year three Research Scholarships, one Graduate Scholarship, and six Student Scholarships, as follows: Research Scholarships, Oliver Lodge, value £420 for one year, may be extended for a second year; I.M.E.A., value £420 for one year, may be extended for a second year; Swan Memorial, value £250 for one year. Graduate Scholarship, for full-time postgraduate study, Silvanus Thompson, value £400 for one year. Student Scholarships, for study at undergraduate level at a University or a Technical College: Silvanus Thompson, value £200 per annum for three years; Manville, value £150 per annum for three years; W. B. Eason, value £120 per annum for two years; Salomons, value £60 for one year; Paul, value £50 per annum for two years; Thornewood, value £25 for one year. The closing date for the receipt of applications is May 1, 1954, for Student Scholarships and June 1, 1954, for Graduate and Research Scholarships.

Full particulars of the conditions of award attached to each scholarship and nomination forms may be obtained on application to the Secretary, The Institution of Electrical Engineers, Savoy Place, London, W.C.2

FOR SALE AND WANTED

X-RAY SET. NEWTON VICTOR RAYMAX Rotating Anode Crystallographic Unit, output 50 mA at 90 kV to 85 mA at 50 kV continuous. Designed for all types of crystallographic work, including diffraction, spectrography, and structure analysis. Equipment includes two Powder Cameras. New in 1952, and scarcely used since. Write for full details to Box 848, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

LABORATORY, SMALL BUT WELL stocked, by London school.—Apply, Box 855, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

ZEISS SLIDING MICROMANIPULATOR for both left and right hand operation, universal base, and special adaptor for Leitz stand. Single and double needle holders and needle clips, all in cases. New, recently imported at £130, offered at £100.—Box 861, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1

REQUIRED, A VAN SLYKE & NEILL manometric apparatus suitable for accurate estimation of alpha amino-acids.—Box 851, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

FOR SALE 43 COMPLETE VOLS. Ministry of Agriculture Journals 1911 to 1953.—Apply, Box 856, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1

MSE 'medium' centrifuge

1 Litre capacity

*speeds up to
4,000 R.P.M.*

A bench model, the "Medium" has a maximum capacity of 1,000 ml when using slotted cups and 600 ml. with metal buckets; it can take up to 54 small glass tubes in multiple carriers. It is a general-purpose centrifuge for both day-to-day and specialized work. A useful choice of interchangeable "Swing-out" and "Angle" heads, a Superspeed Unit and continuous action "Basket" Heads make the MSE "Medium" Centrifuge an extremely versatile machine.

FOR YOUR FILE: MSE make the biggest range of centrifuges in the world in both refrigerated and non-refrigerated types. A brief review of all of them is given in Publication 888. Write for your copy.

Special purpose Cathode Ray Tubes for Research and Industry

A range of cathode ray tubes is available for use in specialised applications such as the observation and recording of high speed transient phenomena, where the high capacitances and other limitations of the usual type of instrument tube would result in distortion or complete suppression of the trace.

Typical applications of these special tubes include high voltage cable testing, insulator overload and breakdown testing, cable fault finding by quasi-radar technique and the investigation of high voltage switching phenomena. They are also suitable for use in laboratory oscilloscopes.

Brief details of some of the more popular types are given below. The tubes are of the all-electrostatic type, with heater ratings of 4V, 1.0A (approx.).

401 CAHA 408 CAHA

Rating.
Va3 (max.) 1.5kV
Vp.d.a.3 3.5kV
Sx (av.) 0.090mm/V
Sy (av.) 0.100mm/V
Screen: 401 CAHA. Green-visual
408 CAHA. Killed blue—photographic
Base: B9G (pressed glass)

4cm. dia. high vacuum monitor tubes with one stage of post deflection acceleration. For use in laboratory oscilloscopes, multi-channel strain-gauge recording equipment, etc.

908 BCC

Rating.
Va3 (max.) 10kV
Sx (av.) 400/Va3 mm/V
Sy (av.) 750/Va3 mm/V
Screen: Killed blue—
photographic
Base: B12D

A 9cm. dia. flat screen high speed recording tube with a low capacitance deflecting system. The connections to the plates and final anode are brought out through side-arms. Writing speeds of the order of 30,000 km/sec. are possible, and transients of the order of 10⁻⁹ sec. may be recorded.

908 CARA

Va3 4kV
Vp.d.a. 8kV
Sx (av.) 0.085 mm/V
Sy (av.) 0.12 mm/V
Screen: Killed blue—
photographic
Base: B12D

A 9 cm. dia. flat screen high speed recording tube with one stage of post deflection acceleration. For use where the special features of the 908 BCC cannot be employed to full advantage. The Y plate connections and final anode are brought out through side arms.

1601 ABC

Va3 (max.) 5kV
Sx 660/Va3 mm/V
Sy 1100/Va3 mm/V
Screen: Green—
visual
Base: B12D

A 16cm. dia. flat screen high speed oscillograph tube. The construction is of the low capacitance type with the deflector plates and final anode connections brought out through side arms.

1608 BCCA

Va3 (max.) 3.5kV
Vp.d.a.3 (max.) 10kV
Sx (av.) 0.15mm/V
Sy (av.) 0.27mm/V
Screen: Killed blue—
photographic
Base: B12D

A 16cm. dia. flat screen tube of similar low capacitance construction as the 908 BCC, but with three stages of post deflection acceleration. This tube will achieve similar writing speeds and recording periods as the 908 BCC, and is recommended for use where the deflecting potentials available are limited.

Alternative screens are available including long after-glow and 'white and blue' aluminised types.

Other types of special tubes are available including:

Double gun tubes. Storage tubes.

Television monitor tubes.

Conical deflection systems tubes for radial time bases. Monoscopes, etc.

Write to Osram Valve and Electronics Dept. for full technical details

THE NATIONAL PARKS COMMISSION

THE fourth annual report of the National Parks Commission*, which covers the year ended September 30, 1953, contains a record of some useful work carried out under disheartening difficulties. Progress is reported in regard to the 'long-distance routes': proposals for a Pembrokeshire Coast Path and for a Cornwall South Coast Path were submitted during the year and the former has been approved by the Ministry. It is clear that the Commission's advice on development questions is being freely sought; the Commission was successful in securing a modification, acceptable to all parties, of the route originally proposed for the 275-kV. grid line from Newcastle to Carlisle, which was to run through part of the area suggested by the Hobhouse Committee as the Roman Wall National Park. It has been less successful in the defence of the Peak District National Park against encroachment of mineral working, especially limestone quarrying. Except for his decisions on the Gantrees Hill and Hartington new proposals, and the reopening of the Cotterhole working, the Minister of Housing and Local Government's decisions were far removed from the recommendations of the Commission and those of the Peak Park Board. The Commission is also manifestly uneasy about the Services land requirements; here again it would appear that the Services have been allowed to judge their own cause and to claim, as essential to defence, areas of great natural beauty in which such developments are clearly undesirable.

Despite, however, the existence of a considerable measure of goodwill, manifested, for example, in the numerous examples of development proposals handled by the Commission, as detailed in Appendix B to this report, the Commission's fourth report is a record of frustration and disappointment which may well prompt the question whether it was worth while establishing the Commission at all.

So far as the public is concerned, it is clear from the Commission's fourth report that there are still widespread misapprehensions as to the nature of a national park, and the effect of designation of an area for that purpose on public access or on farming and other activities in the area. Some at least of the opposition to the Commission's proposals for designation is due to such misconceptions, and it might in practice be sounder policy to concentrate on the task of education rather than, as the Commission itself seems inclined to do, to accelerate the process of designation. It is true that the Commission is naturally and rightly anxious to complete the process before spoliation or encroachment by public bodies has gone so far that irretrievable damage has been done to the areas indicated in the Hobhouse Committee's report. Nevertheless, designation alone is ineffective unless an appropriate administrative authority is created. So long as the Minister of Housing and Local Government and also Parliament refuse to face this issue,

* National Parks Commission. Fourth Report for the year ended September 30, 1953. H.C.18. (H.M.S.O., 1953) 2s. 6d.

local authority parks such as we are now being given cannot be protected adequately against the inroads of government departments and public corporations.

The creation of the North York Moors National Park brought the total area of the six national parks in England and Wales to some 3,400 square miles. Since the report was signed, the chairman of the Commission has signed, on December 7, 1953, an order designating some 680 square miles in the North and West Ridings of Yorkshire, while on January 27, in spite of the opposition of the Devon and Somerset County Councils, to which the report refers, an eighth area was designated in the Exmoor National Park. The Commissioners, however, in this report record some disappointment at the progress now being made in the designation programme; and in the main this disappointment appears to be due to the greater reluctance now encountered on the part of local authorities to concur in the designation of national parks within the area of their responsibility.

One example is Exmoor, already noted. Another instance is to be found in the proposals for a Cornwall National Park. Consultations with the eighteen local authorities concerned began in June 1952, and, as the report notes, the proposal of the Commission that the county's coastal territory should be designated a national park received a warm welcome. In spite of this, local doubts and reservations eventually led to a recommendation of the Cornwall County Council that the project should be deferred *sine die*. The Commission replied that it could not acquiesce in the suggestion that the intentions of the National Parks Act, as the Commission interprets them, should be suspended in this way in Cornwall, and although the County Council declines to comment on the boundaries proposed for the park, the Commission proposes to renew discussions at the appropriate time.

The Commission's disappointment arises in general from the fact that previously such reluctance to consider readjustments in local administration involved by the Act as a corollary to the designation of any given area had usually been overcome more or less successfully. It now appears that not only do misapprehensions as to the purposes and effects of the national parks persist and prejudice the reception of proposals, but also that the economic atmosphere is more unpropitious, for local rates have risen and increased the unwillingness to countenance change. Generally speaking, the Commission believes that the administrative consequences account for the reluctance of local authorities to implement the National Parks Act in their areas. It is not easy to demonstrate to those who are suspicious or sceptical even the short-term and palpable advantages accruing to local rate-payers from the designation of a national park in their area. Although, the report continues, the parks now in operation are taking in their stride, as it were, the anomaly of local authorities carrying the burden of responsibility for a national park, it remains an anomaly which becomes more of a stumbling block to new entrants to the scheme in times of financial stringency.

The National Parks Commission makes no criticism of Government policy; but it is perfectly frank and realistic. Its fourth report makes it crystal clear that the present unsatisfactory position is due to the failure of the Minister of Housing and Local Government to deal with the critical issues of finance, administration and local government reform. If the latter issue were handled with imagination and sympathy as well as wisdom, neither the financial nor administrative obstacles to the implementation of the National Parks Act would be so serious. In the absence of such reform, the intentions of the Act cannot be implemented.

There is no suggestion in this report that the views of the local authorities are to be disregarded. The Commission recognizes as clearly as the Minister himself that the success of the concept of the national parks scheme in Britain depends upon the willing co-operation of the local authorities, and it is anxious to proceed with the utmost degree of agreement attainable between the local authorities concerned and itself. In fact, the brightest feature of this report, as of the preceding report of the Commission, is the evidence it contains of a large measure of co-operation and goodwill.

A conspicuous example is to be found in the Peak Planning Board, which has won the warm support of some who originally opposed its formation. Generally speaking, the Commission believes that the planning boards or committees which have come into existence during the past three years are exercising their powers with growing resolution and with effect. Liaison between them and the Commission is growing, and the Commission takes the reasonable view that these boards and committees must be allowed time to grow. Spectacular or immediate results should not be demanded of them or of the Commission, but nevertheless the inherent limitations in the structure of the boards and in the powers of the Commission should be kept in mind: it is only subject to those limitations, and not according to the full intentions of the National Parks Act, that claims of amenity and beauty and of recreational facilities are being safeguarded.

The details of administrative arrangements in the six areas thus designated as national parks given, without further comment, in an appendix to this fourth report, show the magnitude of the deviation from the arrangements laid down by Parliament in the Act. The success of the Lake District Planning Board and the Dartmoor National Park Committee in dealing with specific matters such as caravanning and camping does not alter the fact that these and other park planning boards and committees have neither the constitution nor the independence which would enable them to take a national point of view, or the authority to resist encroachment, which Parliament intended they should enjoy.

There is thus good reason for welcoming the national campaign for the full operation and ultimate amendment of the National Parks and Access to the Countryside Act, which was launched at a week-end conference at Longshaw House last autumn, convened by the Ramblers' Youth Hostels,

and Co-operative Holidays Associations and the Holiday Fellowship. Informed public opinion and its influence on Parliament are the surest means of securing that the intentions of the original Act are implemented or any satisfactory amendments made to that Act. As Mr. A. Blankinsop pointed out at the conference, not much help can be expected from Parliament until the objectives of national parks are widely understood and more general enthusiasm is manifested for them.

The first need, accordingly, is, as has already been indicated and as was recognized at this conference, for a positive educational campaign on the part of the National Parks Commission and of the rambling and amenity organizations concerned. If the Commission's efforts are still hampered by lack of funds, the voluntary organizations could render valuable help in this task. Quite apart from the fact that, as the conference agreed, these organizations sometimes need to improve their own outlook, co-operation in the task could help to bring home to a large section of the community that a price has to be paid for amenity, and that ultimately the existence and effectiveness of national parks in Britain depend on the effort and resources the community is prepared to devote to that purpose.

Such an educational campaign must obviously include local authorities; their understanding and co-operation are essential if the objects of the national parks are to be achieved, though in the main it is through Government action, both financial and in regard to local government reform, that the reluctance of the local authorities to co-operate will be removed. On the second point, indeed, as is becoming apparent through the foot-paths survey and through the liaison between the Nature Conservancy and local nature reserves, the administration of the national parks offers an opportunity which, used with imagination, could bring fresh vitality to the local units. On the question of finance, Lord Chorley maintained at the conference that the national parks should get at least £1 million a year and that the Hobhouse Committee had been led to expect at least that amount.

Meanwhile, we can expect no more than that the National Parks Commission will be able to prevent irreparable damage until such an educational campaign as was projected at Longshaw has the appropriate effect on public opinion. Since the present report was published, the waterworks committee of one of our largest conurbations, without the knowledge of the city council and disregarding the findings of the Committee on Gathering Grounds and the intentions of Parliament, has sought to obstruct access to the Pennines and to get the decision of the National Parks Commission on the Pennine Way overridden by direct approach to the Minister. If, however, it proves impossible to rouse public opinion to insist that Parliament should no longer allow the purposes written into the existing Act to be flouted, repeal of the National Parks and Access to the Countryside Act would seem to be the wiser course. Respect for the law would then no longer be undermined by official indifference or local obstinacy, and a salutary check might be given to the disposition in a modern democracy to expect that

benefits can be obtained without either payment or effort on the part of beneficiaries. National parks, as the Commission observes in this fourth report, are not museum pieces. The danger, however, is not of stagnation on the part of the Commission but rather of inaction on the part of Government. Only an upsurging of public opinion, fully aware of what is at stake and prepared to pay the price involved in terms of finance or other resources, of legislation and of unceasing vigilance, is likely to bring Parliament or Government to the sense of urgency and to the action required to ensure that the prospect opened up by the successive reports of the Hobhouse and Huxley Committees does not fade away and the national parks and nature reserves prove no more than a mirage.

THE ACCRETIONARY ORIGIN OF COMETS

The Comets and their Origin

By R. A. Lyttleton. Pp. x+173+13 plates. (Cambridge: At the University Press, 1953.) 25s. net.

THE primary object of this book is the exposition of Dr. R. A. Lyttleton's own very interesting theory of the origin of comets, and he has set out "to lay this theory before as wide a circle of astronomers as possible". To render the book complete in itself, he has wisely decided to include an account of the main observational features of comets, and the first two chapters accordingly summarize our present knowledge of their dynamical and physical properties. There follows Chapter 3, which gives the core of the author's theory. He applies the theory of accretion to the passage of the sun through an interstellar dust cloud, and he finds that the result will be the formation of aggregates of interstellar dust describing nearly parabolic orbits around the sun. The orbits of these aggregates would afterwards be modified by planetary perturbations. There is no reason to doubt that the sun may have passed through interstellar dust clouds during its history, and Dr. Lyttleton has now shown that the result of such a passage will be the formation of aggregates of cosmic dust which, when quantitative estimates of size and density are taken into account, seem to be remarkably like comets.

The plausibility of this identification is strengthened in Chapter 4. Here Dr. Lyttleton is led to the conclusion that near the perihelion passage of one of his dust aggregates collisions will operate so as to pulverize some of the particles, and in this way dust may be produced which is fine enough to respond to the radiation pressure of sunlight. This very fine pulverized dust would be blown away from the sun and would so form a 'tail'. The reader is here left with the impression that Dr. Lyttleton's dust aggregates formed by accretion look still more like comets.

The last chapter discusses the relation of the author's theory to earlier ideas, and no special comment on this chapter seems to me to be necessary. With regard to the theory as a whole, it must be emphasized that Dr. Lyttleton has gone some way towards working it out on a quantitative basis with the view of the comparison of his aggregates of dust with comets as we know them. So far, the working out seems to support the hypothesis. Naturally, to

quote Dr. Lyttleton's own words, "there is room for further investigation at many if not all points". A good deal of the working-out process is given in some detail in the book, but the mathematics involved is elementary, and the author has fulfilled his aim of catering "for as wide a circle of astronomers as possible". The book is readable, its standard of presentation is high, and there are some excellent plates and a valuable bibliography.

Dr. Lyttleton has made out, to say the least, a good *prima facie* case, and he has every right to expect that his theory be regarded as meriting detailed and searching analysis and criticism. His book is to be commended to all interested in the subject.

W. M. H. GRIMMES

THE PHILOSOPHY OF DESCARTES

New Studies in the Philosophy of Descartes
Descartes as Pioneer. By Prof. Norman Kemp Smith. Pp. xii+360. (London: Macmillan and Co., Ltd., 1952.) 25s. net.

Descartes' Philosophical Writings
Selected and Translated by Prof. Norman Kemp Smith. Pp. vii+316. (London: Macmillan and Co., Ltd., 1952.) 25s. net.

IT is surprising how little of interest or importance has been written in English on the philosophy of Descartes, in view of the extent to which his main writings are still read by students of philosophy in Britain; by comparison, English work on Spinoza, who is now virtually unread, is of far greater significance. Until the publication of Dr. L. J. Beck's "The Method of Descartes" last year there was no large-scale study in English of Descartes's contributions to logic and scientific method, and even now we lack an adequate discussion of his metaphysics. Prof. Norman Kemp Smith's "New Studies" go some way to fill the gap: making full use of the results of recent French scholarship, they examine Descartes's thought stage by stage and show how his preoccupation with first-hand scientific issues led him to enunciate a clear-cut doctrine of method and a bold metaphysical dualism which he later, with doubtful consistency, qualified in the hope of bringing them into more obvious accord with the facts.

As a contribution to the history of thought, the book is interesting if not conspicuously original; read as an independent discussion of some of Descartes's leading philosophical theses, it is less satisfactory. It is well to stress, as the author does, the pioneer spirit which underlay Descartes's enterprise to provide a purely mechanistic physiology, especially when one remembers the state of knowledge at the time. As the "Discourse on Method" makes clear, it was to medicine and mechanics, not to mathematics or even philosophy, that Descartes hoped to make permanent contributions. But it should surely be stressed on the other side that, if Descartes here showed some of the insight of genius, he also betrayed all too clearly the defects of his qualities; for, despite many disappointments, he never gave up the idea that a final science of Nature could be arrived at, and, as Gilson and others have demonstrated, he never gained a sufficient understanding of the importance of facts. Hence his account of scientific method is at once strikingly right and alarmingly wrong.

But it is when we turn from logic to metaphysics that the defects of Prof. Kemp Smith's treatment

are most obvious. We learn from his book why Descartes was inclined to metaphysical dualism and how his position was afterwards modified by his recognition that (in his own words) "I am lodged in my body not as a pilot in a ship; but so intimately conjoined, and as it were intermingled, with it, that with it I form a unitary whole". There is an interesting discussion of what the author calls "natural beliefs" in this connexion, in which it is argued that Descartes anticipated Hume, but nothing whatsoever is said of the attacks made in recent years on Cartesian metaphysics as resting on a series of "category-mistakes". It may be that these attacks are crude, but they are not too crude to be taken seriously. Similarly, Descartes's "hyperbolic" doubt is expounded in his own terms, and the limitations with which he used it are clearly brought out; but no attempt is made to meet the criticism of this sort of scepticism expressed by writers like Wiedem. Nor are the logical subtleties of the *cogito* argument explored as they deserve to be.

Prof. Kemp Smith has supplemented his "New Studies", which replace an older volume of his published fifty years ago, by a new translation of a selection of Descartes's philosophical writings. He has done this, he writes, because he finds existing versions, whatever their merits, to be written with insufficient understanding of Descartes's views and often with insufficient attention to the nuances of his vocabulary. These are good reasons for making fresh translations, and when the translator is as practised and successful as Prof. Kemp Smith the work is doubly welcome. It is perhaps a pity, however, that he did not offer to revise and expand the Cambridge translation by Haldane and Ross instead of producing a volume which is necessarily incomplete; and he might well have confined his notes entirely to philological matters and abstained from comment on matters of substance, seeing that his comment has to be highly selective and in fact varies considerably in bulk from treatise to treatise.

W. H. WALSH

THE WORKS OF GEORGE BERKELEY

The Works of George Berkeley, Bishop of Cloyne
Edited by A. A. Luce and Prof. T. E. Jessop.
(Bibliotheca Britannica Philosophica.) Vol. 5: *Siris*, *Three Letters to Thomas Prior, A Letter to the Rev. D. Hales, Farther Thoughts on Tar-water, Varia*. Edited by Prof. T. E. Jessop. Pp. xi+236. (London and Edinburgh: Thomas Nelson and Sons, Ltd., 1953.) 30s. net.

THE fifth volume of the new edition of Berkeley consists of his last major work, with minor writings related in subject-matter. "Siris" advocates practical therapeutic measures in terms of scientific theories now obsolete, depending on philosophical concepts now almost forgotten. In its own day "Siris" was Berkeley's most popular work. His tar-water, which long survived in the "Pharmacopoeia" as *aqua picis*, served a useful purpose—a mild antiseptic for internal or external application that could do no harm and might do much good in many common ailments. It could be prepared by any housewife from common ingredients at trifling expense. It is true that Berkeley thought of it as a

panaceas, but panaceas were still respectable. In his arguments he used the best available medical knowledge. These arguments were much better than those for the Brunonian system of therapy, which had some professional support later during the eighteenth century, and as good as those for the homoeopathic system which enjoyed considerable popularity during the nineteenth century. But his arguments were based on alchemical concepts and are now almost unintelligible. They are interesting, though, because they bring out very clearly the underlying metaphysics, from which alchemy derived its genuine, as apart from its fraudulent, appeal.

This metaphysics is the ancient faith in the Great Chain of Being, a faith practically universal in folklore and prevailing in most Greek philosophy. Even the atomist Lucretius, who should have repudiated it, is strongly tinged with it. It is well summarized in a sentence from one of the early "Hermetic" works which Berkeley quotes. "All parts of the world vegetate by a fine subtle ether, which acts as an engine or instrument, subject to the will of the supreme God". It requires only the further statement, that there is one universal material substrate which this ether informs or transforms, striving to bring into existence more perfect from less perfect forms. Any modern who is shocked by this kind of view should read Newton on natural transformations in Query 80, appended to his "Opticks". He should note that where he differs from Newton and Berkeley is in the metaphysics he uses to order the evidence before him far more than in the evidence itself, which could all be taken in alchemical terms.

Prof. T. E. Jessop provides a useful introduction, in which he disposes of the claim that the thought of "Sirius" is inconsistent with Berkeley's earlier works. He has also hunted up the often very obscure references given in the text, and has printed in an appendix the passages in Boerhaave's "Elementa Chemiae" of which Berkeley makes extensive use. Altogether, it is a volume of which editors and publishers may well feel proud. A. D. RICHARDS

BAND SPECTRA OF DIATOMIC MOLECULES

Tables de Constantes et Données numériques

5: Constantes sélectionnées. Atlas des longueurs d'onde caractéristiques des bandes d'émission et d'absorption des molécules diatomiques. Établi par R. F. Barrow, A. D. Camt, A. R. Downie, R. Herman, E. Hultdt, A. McKellar, E. Miescher, B. Rosen et K. Wieland. Pp. 390. (Paris: Hermann et Cie., 1952.) 5600 francs.

FOR atomic spectra, tables of collected measurements of lines arranged in order of wave-length are of considerable value for identification; indeed, books such as Kayser and Ritzsch's "Hauptlinien" and Harrison's "M.I.T. Wavelength Tables" are indispensable. There is a natural tendency to attempt a similar project for the banded molecular spectra. However, the problem is different and much more difficult. Whereas individual lines can often be measured with great precision, band spectra are more often observed with rather small dispersion, and the accuracy of measurement is much less. Even with big dispersion, the exact location of the band heads is complicated by the rotational fine structure of the bands, the choice of head position

often depending to some extent on the instrument used, the source in which the band is excited and even on the observer. Often, too, there are complications due to overlapping rotational structure from another band. Whereas for atomic spectra each main electronic transition is responsible for a single multiplet of relatively few lines, with molecules each transition leads to a whole band system, and it is usually preferable to try identification of systems rather than of individual bands.

Volume 4 of "Tables de Constantes sélectionnées" was produced in 1951 by the same authors as the present volume, and contained a very useful collection of data of the spectra and molecular constants of individual diatomic molecules. The present volume is essentially a supplement to this, and most of the previously listed bands, with a few more from recent literature, are grouped into one table, containing nearly 18,000 heads of 299 molecules. They cover the wave-length range 15,050–672 Å. For each band, the direction of degradation, emitting molecule, electronic transition (where known), vibrational transition, and up to four of the characteristic or strongest bands of the system are listed. No indications are given of the appearance of the band (that is, how many heads), the type of sources in which it may be expected or intensity relative to others of the system. The term "Atlas" should not be translated literally; there are no photographs or diagrams. The volume also includes wave-length lists, involving 2,500 heads, of bands of C_2 , OH, OH^+ , CN, CO, CO^+ , N_2 , N_2^+ , NH, NH^+ , NO, O_2 , O_2^+ , OH and OH^+ separately; these are mere lists of wave-lengths without indication of direction of degradation, system or intensity, and it is difficult to imagine any use for them. The volume also contains a list of about four thousand lines of H_2 , with their transitions.

It is natural to compare this volume with Pedree and Gaydon's "Identification of Molecular Spectra", an earlier attack on the same problem. This also included a much shorter list of principal band heads in order of wave-length, but relied mainly on photographs and individual tables. The present volume has the advantage of including the photographic infra-red and far ultra-violet regions, but the disadvantage that it is strictly limited to diatomic molecules, whereas Pedree and Gaydon included the main triatomic and polyatomic molecules and also gave indications of band appearance and sources in the main list. The much greater size of the table in the volume under review is not necessarily a big advantage. In the main visible and near ultra-violet region there are three or four bands to an angstrom, so that with the normal accuracy of measurement several chance coincidences will inevitably occur for each band head. In many cases the selection of material seems poor. Thus, as examples, about fifty heads of BaBr are listed around 5400–5150 Å., whereas the six main sequence heads should be sufficient; for the extensive $B \rightarrow X$ system of Te_2 , about a hundred heads are included. This does not really make identification more certain; it merely confuses the issue by increasing the number of chance coincidences.

The volume can, of course, only be made use of in conjunction with the previous Vol. 4, and in view of the limited usefulness of tables of this kind, unless supplemented by photographs, the high price would seem to put it in the luxury rather than the utility category. A. G. GAYDON

Elsevier's Encyclopædia of Organic Chemistry
 Edited by F. Radt. Series 3: Carboisocyclic Condensed Compounds. Vol. 14, Supplement, Triterpenes. Co-edited by Dora Stern. Pp. xxxii+939S-1346S+Ind. 50. (New York and Amsterdam: Elsevier Publishing Co., Inc.; London: Cleaver-Hume Press, Ltd., 1952.) £11 to subscribers.

IN the original Vol. 14 of this "Encyclopædia", published in 1940, 85 pages were devoted to a survey of the chemistry of the triterpenes. The fact that 407 pages of this supplementary volume are needed to summarize the literature belonging mainly to the period 1937-46 reflects the enormous amount of attention given to this considerable group of natural products during the decade. There seems every justification for the claim that the literature concerning the structures of the compounds is covered up to 1952. To a very large extent these structures have now been fully established, and several of the major groups of triterpenes have been inter-related. A number of gaps could now be filled by work which has been published since the appearance of the present volume, and much could now be written of the stereochemical relationships, which receive scarcely any mention.

The general characteristics of Elsevier's "Encyclopædia" are now so familiar that it is unnecessary to reiterate them. The usual excellence of production is maintained, and the features which are especially attractive in this volume include the following: the elaborate but beautifully clear charts illustrating conversions and reactions of the various groups of triterpenoids; a systematic list of compounds arranged according to the carbon skeletons which their molecules contain; and an alphabetical list of natural triterpenoids, grouped together in the index. It is quite an achievement to have found a misprint: this occurs in the first line, where the year 1945 is erroneously given as 1941.

It is a foregone conclusion that this volume is now in constant use by all workers in the field. It is safe to predict that it will also arouse the interest of a much wider circle of chemists.

Advanced Experiments In Practical Physics

By J. E. Calthrop. Second edition, revised throughout by Dr. J. A. Pryde. Pp. xvi+144. (London: William Heinemann, Ltd., 1952.) 10s. 6d.

IT is a pleasure to welcome the revised version of Mr. J. E. Calthrop's excellent book, even though it was not possible for this revision to be done by the original author. In producing the second edition, Dr. J. A. Pryde has accomplished a not too easy task in a very satisfying way, and, as is inevitable in such cases, certain alterations have been made, particularly in the section on electricity and magnetism, while new experiments dealing with valves, dielectric constant, conductivity and thick lenses have also been included.

To those who are not acquainted with Mr. Calthrop's book—and surely there can be few honours physics students in Britain who are not—it is only necessary to suggest that they should remedy this deficiency without delay. The book is designed specially for honours students and contains a series of fifty-five experiments grouped in three sections; and although the experiments vary in their standard of difficulty, each one is interesting and should be of inestimable benefit to the student from the point of

view both of acquiring knowledge and of improving technique in practical work. The book concludes with a collection of additional problems and a list of useful books on the practical teaching of physics.

The standard of work set and presented by Mr. Calthrop was very high; the new edition certainly preserves that standard, and the book can be thoroughly recommended.

General Topology

By Prof. Wacław Sierpinski. Translated by O. Cecilia Krieger. Second edition. (Mathematical Expositions, No. 7.) Pp. xii+290. (Toronto: University of Toronto Press; London: Oxford University Press, 1952.) 48s. net.

STARTING with the definition of a Frechet (F) space, and making no assumptions concerning the 'neighbourhoods' involved in the definition, Prof. W. Sierpinski proceeds, in Chapter 1, from derived set to closed and open sets. The open sets so defined are seen to satisfy the axioms for a topological space except that the intersection of two open sets may not be open. With these 'minimum' assumptions, several theorems on continuity, separation, connectedness and compactness are established; these extend considerably the results in Chapter 1 of the first edition of the book.

In Chapter 2, axioms for a topological space are assumed. After spaces the topologies of which have a countable base have been considered, Hausdorff spaces which satisfy the first countability axiom are studied; this makes a change from the first edition.

The remainder of the book covers approximately the same ground as the first edition, but with some deletions, some additions, and several improvements, notably in the shape of problems and examples. There are also changes in terminology to conform with standard usage introduced since the first edition was published.

The appendix by O. C. Krieger on cardinal and ordinal numbers is almost unchanged from the first edition. R. G. COOK

Calculus

By Prof. O. R. Wylie, Jr. Pp. x+565. (London: McGraw-Hill Publishing Company, Ltd., 1953.) 48s.

THE distinctive feature of this first course in calculus is the great care taken by the author to make the subject interesting and intelligible to students of limited ability and small preliminary knowledge, who are told in advance the objective of each discussion, why a particular method is used, and what pitfalls have to be avoided. It is commendable that the author has scrupulously avoided the unsound arguments that occur in many elementary books. When the sound proof is too difficult for the beginner to understand, the theorem is stated without proof, for which a reference is given to a more advanced book.

The first chapter gives an excellent general outline of the leading ideas of both differentiation and integration. The later chapters go beyond most first courses, and include some account of physical applications, partial differentiation, multiple integration, Fourier series and differential equations. There are a great many examples (all with answers), a summary at the end of each chapter, an index, tables, formulae from other branches of mathematics, and a glossary of technical terms. The only defect of the book is its high price. H. T. H. PRAGGIO

THE ELECTRON MICROSCOPE IN BIOLOGY*

By Dr. RALPH W. G. WYCKOFF, For.Mem.R.S.

Science Attaché, American Embassy, London

TWO recent developments in the human mind have contributed to produce modern natural science. One is a more acute sensory perception and objective awareness of the outer world. The other is an equally striking enlargement of the intellectual ability and willingness of many men to deal with these clearer perceptions of Nature, to relate them logically one to another and to devise from these relationships a consistent pattern of outer happenings. This enhanced sensory awareness of external reality expressed itself in the painting and sculpture of the Renaissance; and more or less simultaneously there arose, sometimes in the same individual, that closer and more purposeful observation of natural phenomena which was a root of modern science. In art this clearer perception enriched immeasurably the world of human values which art serves; in science it began to furnish that basis of external fact which must underlie any sound understanding of the meaning of human existence.

Only a rudimentary natural science could, however, have arisen from such unaided observation, no matter how acute, or how carefully it was analysed. The intimate knowledge we now possess of the texture of the universe is the direct result of the invention and use of instruments to extend and render ever more quantitative the limited information our senses can supply.

Vision is, of course, the sense that has taught us most about Nature; and it is therefore natural that instruments which extend its range will have been most actively sought and most highly valued. It was the telescope that gave a first practical demonstration of the essential role of instruments; the microscopes that began to be made soon after started the equally important observation of fine structure which has now become the chief preoccupation of modern science. Every branch of science seeks first an accurate description of the gross appearance and behaviour of its segment of Nature; and this has customarily been followed by the attempt to analyse the matter that is present into its components and to ascertain significant relations between these components and the gross properties with which the original description was so largely concerned. In chemistry, this analysis has been achieved through the interpretation and correlation of elaborate series of chemical reactions. For certain other sciences, the microscope has been a much more direct analytical tool. Thus, the analytical stage for biology may be said to have begun when compound microscopes made accessible for study the individual cells that are the unit structures of living matter.

Since then, there has been a steady improvement in techniques of microscopy which, though providing very little extension in vision, have yielded a steady flow of new knowledge about the cellular level of organization. In our day, the electron microscope is

of such exceptional importance because it does give such an extension, and one that allows us not merely to see smaller detail but also to reach in biology the deeper and more fundamental level of organization where molecules are the units. For the past twenty-five years we have known that the proteins and many other substances extracted from living matter have very large molecular particles. A number of these particles have already been seen under the electron microscope, and the fact of this visibility takes us beyond chemistry's conventional concern with statistical molecular aggregates to observations on separate molecules and their interactions. It is the principal object of this discourse to illustrate some of the more immediate applications we have made of this ability to see macromolecules.

Before doing this, however, I must give some idea of the great extension in vision already achieved with this new microscope. The limiting resolving power of any optical system defines its ability to portray small objects: it depends on the wave-length of the illumination we use. Optical theory has demonstrated that no microscope can possibly reveal the true shape of an object smaller than about half this wave-length. Accordingly, visible light cannot delineate objects smaller than c. 0.2 micron (about a hundred-thousandth of an inch); with ultra-violet light we can do little better. Electron microscopes, though only about fifteen years old as scientific instruments, have already portrayed objects more than a hundred times smaller than this in linear dimensions and hence more than a million times smaller in volume and weight. Such tiny particles are only five to ten atoms across. The newly visible world having such relatively small molecules as its lower limit is about as extensive, and as full of unknown things, as that aspect of Nature which the optical microscope first brought to light. It will take a long time to discern all that is here, and still longer fully to understand what we are seeing. In the meantime, we have all the excitement of seeing what no man expected to see, and of using much of the new knowledge thus gained to approach with clearer understanding many of biology's essential problems.

An indication of the relationship of the electron microscope to the familiar optical microscope may help in interpreting the images it produces. Seventy-five years ago, in 1879, Sir William Crookes demonstrated in the Royal Institution various forms of his new cathode-ray tube. The electron microscope is such a tube in greatly elaborated form. Like the Crookes tube, it has a source of electrons and a fluorescent screen to show their pattern; a magnetic field is commonly used to change their direction. In the electron microscope there are several of these fields, and they are so arranged that the electrons follow paths through the tube that imitate the path of light through the glass lenses of an optical microscope.

From a consideration of what an electron microscope is, it will be realized that there is no compelling technical reason why we should not have had some

* Substance of a Friday Evening Discourse at the Royal Institution delivered on December 11. The Discourse was illustrated by a series of electron micrographs from among which the accompanying figures were taken; an electron microscope was also demonstrated and its images shown to the audience on several television receivers. This demonstration was arranged through the courtesy of Philips Electrical, Ltd., and R. M. Industries, Ltd.

Fig. 1. Early stage in the crystallization of a necrosis virus protein. The orderly arrangement of the particles is apparent. $\times 40,000$

form of this instrument many years ago. Probably it was not built because its advantages become obvious only when our realization of the wave qualities of the electron started people thinking about it as an illuminant. Here is, in fact, a rather striking example of how our scientific imaginations may be bound by the ideas current at any time.

In science, as in most other fields of human endeavour, we rarely get everything we would like, and accordingly, it should not be a surprise that there are important limitations to what can be looked at under an electron microscope. For the most part these arise from the relative impenetrability of matter by electrons; therefore, the object must be extremely thin and, after thorough drying, it must be examined under the vacuum of the tube. This is not an overwhelming disadvantage; but it makes necessary new methods of specimen preparation that will preserve the structures we are interested in, down to their finest molecular details.

To delineate very small objects we must look at their very highly magnified images; this involves magnifications far greater than those useful in optical microscopy. The detail seen in the best optical microscopes becomes increasingly 'fuzzy', indistinct and meaningless when viewed at magnifications above about $1,500\times$; but we can now have electron micrographs in which detail is sharp at $150,000\times$. Occasional electron micrographs are worth studying at twice this magnification. These magnifications are so vastly in excess of any in our previous experience that most of us find it difficult to have a vivid realization of how very small are the objects we are seeing.

Many novel problems arise when we use the electron microscope to see molecular particles. In it, objects are visible by reason of the electrons they deflect, or scatter; and a molecular particle is able to deflect very few compared with the substrate that must be used to support it. This lack of a necessary contrast in the resulting image can be met by evaporating a few atoms' thickness of heavy metal obliquely over a preparation. Then contrast is enhanced by the little atomic shadows cast by molecular and other detail, and these have the added advantage of giving the image a three-dimensional quality that reveals the shapes of what we see.

There is one very important difference between the practice of optical and of electron microscopy, made necessary by the destructive effects of powerful electron beams. In general, the optical microscopist does most of his work visually and only occasionally takes a picture. The electron microscopist, on the contrary, uses visual images mainly to find and to focus on fields of interest. By then taking pictures on fine-grained photographic film and enlarging them later, he is able to obtain very high useful magnifications without employing the destructive electron intensities that would be needed to give bright images at these highest enlargements.

It is impossible to do more here than show what a few typical macromolecular particles are like, and indicate some of the problems dealing with them that are now claiming our attention. In essence these problems are threefold. They involve recognizing and measuring the particles, determining how they are arranged in the structures they form, and trying to find out how they are produced in Nature.

The proteins that occur in solution in a living organism offer many examples of approximately spherical macromolecules. When sufficiently purified, these substances often crystallize well, and we can study with the electron microscope various stages in

Fig. 2. Section through a swollen tendon. Two or three unswelled fragments show their characteristic striations. $\times 21,000$

the growth of the single crystals they form. The photographs that have been obtained from a number of proteins and plant virus proteins show the beautiful molecular order that characterizes all steps in crystal formation (Fig. 1).

Another highly important type of molecular particle is a long filament. The thicker among these are relatively stiff and straight, like the tobacco mosaic filaments in old solutions or the elementary particles of cellulose. Those that are thinner are wavy threads. Solutions of the muscle proteins, of collagen from connective tissue and of the nucleic acids contain such threads; some that have been photographed are less than ten atoms in diameter. Paracrystalline, rather than crystalline, solids composed of these filamentous macromolecules are among the important framework structures of plants and animals. Their investigation is one of the most rewarding of the current applications of electron microscopy. Filaments display a striking tendency to assume parallel arrays. Thus, the secondary walls of plants consist of stacked sheets of parallel aligned filaments of cellulose. Striated muscle has a parallel alignment of molecular threads as a sort of backbone for its other components. Sections cut at right angles to a muscle fibre demonstrate many fine details of an ordered packing of these threads that in some places is almost crystalline in its perfection. Evidently the kind of knowledge that will result from such observations permits an entirely new approach to the problem of muscular contraction.

An equally good but very different type of molecular order prevails in tendon and other forms of connective tissue. Collagen, for example as Achilles tendon from the heel, has been examined as shredded fragments and in sections cut in various directions through an intact tendon. At low magnifications not much above those used in optical microscopy, one sees the tiny fibrils that are associated together in bundles and sheets to form the macroscopic tendons.

Higher magnifications reveal the fine structure of each component fibril. The examination of transverse sections suggests that a fibril is enveloped by a tube of collagen; preliminary swelling shreds the collagen and shows how its macromolecular particles are knitted together to produce such a tube (Fig. 2). Collagen dissolves in very dilute acids and alkalis and can be re-precipitated from its solutions. The electron microscope demonstrates that under certain conditions these re-formed fibrils have the molecular fine structure of the original collagen, but that under other conditions of precipitation fibrils of different fine structures are produced. Some of these are found in Nature, others are not. Such investigations of the various forms of collagen are important, not only for their bearing on the nature of paracrystalline order, but also because they permit us to study the changes in connective tissue that accompany and perhaps may sometimes be responsible for arthritis, rheumatism and similar degenerative diseases of man.

When we seek to deal with the third broad field of study opened up by electron microscopy—how these macromolecular particles arise—we immediately realize the need first for an adequate picture of the fine structure of the living cells that produce them. Most of what we know about the cells that constitute the higher plants and animals has been gained from optical microscopic studies on thin sections of their tissues. To extend our observations to electron microscopic magnifications it has been necessary to learn how to cut sections that are about fifty times thinner than those required for this optical work. Such wafers of tissue only a few millionths of an inch thick can now be cut as a matter of routine. With them we are beginning to survey again some of bacteriology and many problems of histology and embryology from the point of view of the new detail that is to be seen. Artefacts formed during specimen preparation obviously are more troublesome the finer the structures being studied,

and new methods must be developed before we can utilize to the full the potentialities of the electron microscope. Nevertheless, the progress already made has revealed far more than we can yet interpret within sectioned tissues.

Innumerable questions can be answered from the examination of healthy cells. If they are from plants we can, for example, follow the growth of their walls and we can examine the fine structure of their chloroplasts, of their starch grains and of the many other objects to be seen in their cytoplasm. If they are of animal origin, we can inquire into the elaborate mitochondrial and other structures that are particularly striking in cells of special function such as those in the liver or kidney, in the eye or the nervous system. With both plant and animal cells we can approach from this finer level of organization the mechanism of cell division (Fig. 3).

These studies of components of the normal cell and of how they develop supply the background

Fig. 3. Section through an onion root tip showing parts of several resting and one dividing cell with its (sectioned) chromosomes. $\times 7,500$

Fig. 4. A mass of influenza virus particles developed from a cell, the border of which appears along the left edge of the photograph. $\times 8,200$

requisite for investigating the abnormalities of cell life that are responsible for many diseases of living matter. Virus diseases are among the first of these to which we naturally turn, both because the viruses that cause them are too small to have been visible before and because, whatever their nature, these pathogenic agents stand on the borderline between the animate and inanimate and thus offer a unique opportunity of learning more about the essence of the living state.

My laboratory in the United States at the National Institutes of Health has been particularly concerned, over the past few years with this study of virus growth, and we have learned much about how several viruses develop within the cells that are their hosts. There appears to be no uniform pattern for this development, and one cannot briefly describe the various types of virus growth we have seen. Nevertheless, I would like in conclusion to indicate what we have found about one familiar virus—that of influenza. From an examination of purified suspensions, we know that its infectious particles are either tiny spheres or filaments of the same diameter. In sections through diseased tissues we find these virus particles not within the infected cells themselves, as many of us would have expected, but clustered around their peripheries and developing from them as filaments that break off and segment into spheres (Fig. 4). Such observations with the electron microscope demonstrate that the elementary infectious units of this virus have not proliferated after the fashion of minute micro-organisms but instead are bits of cytoplasm of the diseased cells.

The particles of several other viruses, including bacteriophages, are derived from the protoplasm of the host cells; but there are other viruses that do not have such an origin. Some appear to arise from specialized components of the diseased cell, whereas others may be foreign invaders that multiply like micro-organisms, by growth and division. Much more observation is needed before the full story of

virus growth is known; but it is important that we at last have a method capable of giving this knowledge.

At this early stage in our explorations with the electron microscope it is not possible to foresee what new insights into the vital process it will next give us. Perhaps they will come as we address ourselves more and more towards the small viruses, especially those that attack nervous tissue; or perhaps we shall find more immediately rewarding the closer study of the numerous structures that are steadily being found as we examine a widening range of healthy cells. Whichever it is, we may be sure that our visual penetration of the macromolecular level of organization will prove steadily more fruitful as experience gives us an increasing ability to interpret the new things we observe.

CENTRAL LABORATORIES FOR SCIENTIFIC AND INDUSTRIAL RESEARCH, HYDERABAD

Opening Ceremony

THE new buildings of the Central Laboratories for Scientific and Industrial Research, Hyderabad, were opened by Shri Jawaharlal Nehru on January 2, in the presence of distinguished guests, foreign scientists, delegates to the Indian Science Congress and eminent industrialists.

Rashttrapati Rajendra Prasad sent a special message for the occasion, conveying his best wishes for the successful fruition of the endeavour made by the State for the advance of science. He further stated that: "It goes without saying that money spent on research is rightly regarded by all progressive nations as a sound investment made for the common weal. Attempts like these, therefore, deserve all encouragement that the State could give in the interest of human progress and happiness. I congratulate Hyderabad State for establishing these laboratories and fervently hope that those who would have the privilege of working in these laboratories would be inspired by the lofty ideal of rendering service to humanity".

Dr. Husain Zaheer, director of the Central Laboratories for Scientific and Industrial Research, in his address emphasized the importance of regional laboratories working in co-operation with the national laboratories for the overall development of scientific and industrial research in India. The immediate and early exploitation of new inventions, he said, requires a degree of technical skill and finance which is usually not available even in countries like Britain, with the result that a great majority of such discoveries made during the past twenty years were first exploited in the United States. He therefore emphasized that the main activities of the laboratories, at least for some time to come, will be directed not so much towards making new discoveries or inventions as towards developing and adapting already known methods and techniques. Consequently, the work in the Laboratories has been concentrated on developmental work of modern methods and on adapting them to the industrial needs and requirements of this region.

The Prime Minister, Shri Jawaharlal Nehru, in his speech referred to the scientific progress the world has made during the past few years; he said that science has changed the whole world, and this must be accepted by India. While the people in India had begun to realize the importance of science, he believes that there are still many who do not realize the necessity or importance of scientific research. He added that, despite able administration, no country can progress without science; scientists and engineers are far more important than administrators. The administrators have, no doubt, their place, but it is secondary to that of scientists and engineers. It is therefore necessary that scientific research should make progress in India.

Dealing with the division of work among the various laboratories, the Prime Minister said that, for a big country like India, both general and special laboratories are necessary. It is desirable to have the laboratories spread out in different regions so that the scientific outlook should become familiar throughout the country. But, he said, there should be no waste of energy in regard to the work done by these laboratories. One individual or institution cannot do everything thoroughly and efficiently; the standard of work must be maintained at a high level. Duplication of work may sometimes be necessary, but there must be no waste. Mr. Nehru felt that a general laboratory for the south of India was appropriately sited in Hyderabad, and hoped that the work there would contribute to the progress and prosperity of this region as well as of the whole country.

After the buildings of the Laboratories were declared open, the Prime Minister and distinguished guests inspected them and also the cotton-seed processing pilot plant and the pilot plant for the low-temperature carbonization of coal.

General Aims of the Laboratories

The Laboratories were established in 1944 by the Hyderabad Government on the initiative of the Council of Scientific and Industrial Research. But due to unsettled political conditions in the State, the full plan could not be carried out immediately. Dr. S. Hussain Zaheer took charge of the Laboratories as director in November 1948, and submitted a detailed scheme for their organization and development to the governing body. He laid emphasis on developmental and pilot-plant research utilizing the raw materials of the State. The scheme was approved by the governing body in March 1949. The then Military Government took an active interest in the implementation of the plan. Extensive lands were acquired near the Osmania University campus. The foundation stone of the new buildings of the Laboratories was laid by Major-General J. N. Chaudhuri, Military Governor of the State, on November 6, 1949.

The main building is in the shape of a T, with administrative block, the auditorium and the museum forming the two wings and the laboratories forming the central block, which consists of a basement and four floors. The ancillary buildings consist of four large pilot-plant buildings, workshop, electricity sub-station and the gas house.

The first stage, which has been completed, consists of a basement, ground floor (excluding auditorium and museum), first floor, two pilot-plant buildings, workshop, electricity sub-station, gas house and store house for inflammable chemicals, with a total floor area of 86,000 sq. ft. The total expenditure on

buildings has so far been Rs. 21 lakhs. Approximately Rs. 30 lakhs has been spent up to now on pilot plants, equipment and apparatus, etc.

The main purpose of the Laboratories is to carry out developmental research of an industrial nature covering the fundamental as well as applied aspects of each problem. Research problems taken up for investigation are initially put forward by research committees, government departments or industries, or are brought up during discussion between the director and research workers. The problem is discussed in detail in the Operational Research Unit and a decision taken regarding its importance and feasibility. Afterwards, information relating to the availability of raw materials, demand for finished products, their market prices, etc., is collected and a 'literature note' is prepared incorporating all the data available. This note is discussed anew by the Operational Research Unit and a detailed programme of work with a time target is drawn up. On successful completion of the laboratory investigation, the Pilot Plant Committee studies the chemical engineering aspects of the problem concerned in its translation to the pilot-plant stage, and prepares a non-technical note with approximate costings, for circulation among interested industries. Pilot-plant experiments are then undertaken either in the Laboratories or by industries, and an industrial process is evolved on the basis of these trials. The pilot-plant schemes are also sent to the various specialized bodies of the Government of India; like the Indian Central Oilseeds Committee, the Council of Scientific and Industrial Research, the National Research Development Corporation and others.

In the selection of the research programme, every effort is made at all stages to co-ordinate the work with that of the National Laboratories, and care is taken to avoid unnecessary duplication of effort.

Work of the Sections

The *Fuel Section* has concentrated mainly on a detailed study of all aspects of the utilization of the rich and extensive deposits of coal in Hyderabad State. A detailed survey of the coal deposits has been under way during the past three years. Recently, the Council of Scientific and Industrial Research, Delhi, has entrusted these Laboratories with similar work on the available deposits of lignite coal in Madras State. Washability tests on coal of high ash content are regularly carried out in a modern type of heavy-medium separation plant on a semi-large scale. The Tatas are interested in the washability tests of coal and have requested the Laboratories to carry out similar tests on coal from Digwadih (Bihar). A 25-ton/day plant employing the Lurgi process of low-temperature carbonization of coal, the first of its kind in India, has been erected and is in operation for testing non-caking coal of this State as well as similar coal and lignite from other parts of the country. Problems connected with the low-temperature carbonization of coal, such as study of tar, ammoniacal liquor, and recovery of tar acids, benzole, etc., are under investigation. It is proposed to set up, shortly, experimental units for tar hydrogenation and pressure gasification.

The *Heavy Chemicals Section* has, in view of the sulphur shortage in the country, carried out considerable work on sulphates as an alternative source of sulphur. Work on the utilization of the limited deposits of iron pyrites for the same purpose has also been actively pursued. Work on the preparation

of activated carbon from groundnut hulls, potassic fertilizers, activated silica and white cement from feldspar, and phosphatic fertilizers from bone meal have given encouraging results.

The *Ceramic Section* has aimed at the utilization of indigenous raw materials. Systematic studies of Hyderabad clays, including X-ray and base-exchange studies, have been carried out. The methods of manufacture of sand-lime and clinker-lime bricks, insulator bodies, insulator bricks, whiteware bodies and fire-clay refractories have been investigated.

The *Physical Chemistry and X-ray Section* has carried out valuable X-ray studies on the nature of Hyderabad clays and is at present engaged in X-ray studies of other clays and of monazite sand. The section is equipped with modern types of instruments such as ultra-violet spectrographs, petrological microscope, metallographic equipment, etc.

The *Oils Section* has been engaged in extensive studies on sitaphal seed; on cotton-seed (storage of seed, composition of seed and oil, refining of oil and utilization of foots), and on castor oil (detailed investigations on dehydration, isolation of the valuable lubricant triricinolein). Katha (acacetidin) has been found to be an excellent anti-oxidant for edible oils. Methods of fractional separation of fatty acids using urea adducts have been extensively investigated. Several local fuller's earths and clays have shown valuable bleaching properties, and large-scale trials are in progress.

The *Biochemistry Section* has carried out extensive studies on the utilization of molasses, and has aimed at the production of citric acid (using strains of *Aspergillus niger*), lactic acid and calcium lactate, food yeast, and levulinic acid and its salts. Selected strains of *Aspergillus terreus* have been employed for the production of itaconic acid from glucose and sucrose. The protein and non-protein nitrogenous constituents of the seed cake of *Annona squamosa* are also being investigated.

The *Organic Chemistry, Pharmaceuticals and Drugs Section* is working on both natural and synthetic products. Quinazoline-type compounds with potential analgesic activity have been prepared, a new synthesis of pethidine attempted and encouraging results have been obtained in a scheme for the simpler synthesis of diethylstilboestrol. Studies have been carried out on the preparation of strychnine from nux vomica. The fundamental constituents of Indian turpentine are being re-investigated, while chlorinated turpentines have shown outstanding insecticidal activity. The preparation of vanillin from the lignin obtained from paper-mill black liquor has been attempted, and pure geraniol has been prepared from palmarosa oil.

The *Paper and Fibre Section* has been investigating the production of hand-made paper for different purposes, for example, bond, drawing, writing and filter papers, utilizing locally available raw materials. In view of the existence of an acetate-rayon factory in the State, this section has been actively investigating the various cellulosic materials as raw materials for rayon manufacture.

The *Entomology Section* has been testing the insecticidal efficiency of various products prepared in the Laboratories.

The *Chemical Engineering Section* is associated with all pilot-plant schemes of the Laboratories and with the procurement and setting up of equipment. The section has been carrying out extensive studies

on solvent extraction of oil-cakes. It also advises the regional industries in their chemical engineering problems, in addition to helping them in the erection and operation of their manufacturing plants. It has been responsible for erecting the Lurgi plant for low-temperature carbonization of coal and a complete Carver pilot-plant for pretreatment of cotton-seed. The chemical engineering aspects of processes worked out in the Laboratories, such as production of levulinic acid from molasses, of fructose from cane sugar, of itaconic acid from sucrose, of dehydrated castor oil, briquetting of coal, fluidization of coal, fractionation of fuel oil, hand-made paper, refining of palmarosa oil, activation of Hyderabad earths, etc., have been engaging the attention of this section.

The staff comprises the director of the Laboratories (Dr. S. Husain Zaheer), two assistant directors (Dr. S. A. Saletore, one vacancy), 53 scientific officers and research assistants and 52 technical staff.

Reports and Finance

During the years 1950-53, fifty-three papers were published by the Laboratories staff, twelve were communicated for publication, 187 papers were read at various symposia and conferences, seventeen patents were obtained and two patents are pending grant.

The Laboratories organized symposia on fuels, fats and oils and on research and industry in 1950, and later published the proceedings.

Annual reports (since 1950) are published regularly, giving summaries of the items of work under investigation.

The Laboratories strive to maintain close relations with other research institutions in India and abroad, and with industries. Regular visits by members of the staff are paid to various factories; for example, to the Nizam sugar factory, Sirpur paper mills, Sirpur acetate-rayon plant, Singareni collieries, ceramic and glass factories, vegetable oil factories, chemical and biochemical manufactories. Advice is given on both short-term and long-term problems.

The recurring budget of the Laboratories for 1947-48 stood at Rs. 2.74 lakhs; for 1953-54 it is Rs. 4.5 lakhs.

The non-recurring grants actually made available over the past five years include the following:

	Rs.
(a) Building	
From the Government of Hyderabad	16.7 lakhs
From the Government of India	5.0 "
(b) Equipment	
From the Government of Hyderabad	7.1 "
(c) Pilot-plant projects	
Grants from the Industrial Trust Fund, Hyderabad	
Low-temperature carbonization plant	7.5 "
Chemical engineering equipment	2.6 "
Cotton-seed processing plant	1.0 "
(d) Research schemes	
Coal survey	
Grants from the I.T.F., Hyderabad	12,000
Grant from the C.S.I.R., Delhi	22,000
X-ray studies on Indian clays	
Grant from the C.S.I.R., Delhi	6,000
Grant from the Atomic Energy Commission	5,000
Briquetting of non-caking coals	
Grant from the C.S.I.R., Delhi	7,000

A sum of Rs. 1 lakh was given to the Laboratories in 1953 by the Azamjahi and Osmanshahi Mills, Ltd., Hyderabad. This was further augmented by smaller donations of a total value of Rs. 15,800 from other industries. The interest from these sums is being used for instituting research scholarships. Under the five-year plan Rs. 27 lakhs have been sanctioned to the Laboratories but have not yet been made available.

OBITUARIES

Prof. A. G. Ogilvie, O.B.E.

THE sudden death of Alan Grant Ogilvie, who collapsed while attending a meeting of the Royal Scottish Geographical Society on the evening of February 9, takes from our midst one of the few remaining pioneers of the new geography as a university discipline. Born in Edinburgh in 1887, he maintained throughout his life much of the dignity and Victorian charm characterizing his childhood home—the son of a distinguished if austere father, the late Sir Francis Ogilvie. From George Watson's College and Westminster School, he proceeded to Magdalen College, Oxford, taking his B.A. in 1909. Periods of study at the Geographical Institute of the University of Berlin and at the Sorbonne followed, and gave him a command of European languages and a wide range of academic contacts—further extended by geological studies at the Imperial College of Science and Technology, London.

His academic career began in 1912 when he was appointed junior demonstrator in geography at Oxford but was interrupted by the outbreak of war in 1914. Ogilvie had accepted a commission in the 7th London Brigade of the R.F.A. in 1911, so he was immediately called up and served in France, the Dardanelles and Salonika before becoming staff captain at the War Office in 1918. His selection as leader of the Geographical Section of the British Peace Delegation at Versailles was an obvious one. It was there that he began a lasting friendship with Isaiah Bowman, leader of the American Geographical Section. It was often difficult for the few experts present to hide the sometimes abysmal ignorance of the peace-makers concerning the countries and peoples for whom they were legislating. There is no doubt that the state of affairs thus revealed stimulated the establishment of Honours Schools of Geography in most British universities in the decade which followed. Ogilvie was made O.B.E. for his services and was appointed reader in geography at Manchester. The following year, however, Bowman, then director of the American Geographical Society, invited him to New York, and during 1920–23 he was head of the Hispanic American Division of the Society. There he showed his flair for collating work from many and varied sources, evidenced first by his "Geography of the Central Andes" (1922). In 1923 he returned to his native Edinburgh, there to spend the rest of his life, first as lecturer, then as reader (1924) and finally as professor of geography from 1931 until his death.

Ogilvie's writings were neither numerous nor voluminous, but always scholarly and showing evidence of very wide reading. His work as editor and part author of "Great Britain", a series of regional essays prepared for the International Geographical Congress in 1928, remains of lasting value. He served devotedly the Royal Scottish Geographical Society (honorary secretary, 1925–41; president, 1946–50) as well as the British Association (president, Section E, 1934; chairman of Committee on Tropical Africa), the Institute of British Geographers (president, 1951–52) and the International Geographical Union (section president, Lisbon, 1949).

A man of great intellectual integrity himself and not always robust physically, he refused to condone lower standards in others, and perhaps envied the

greater facilities for field-work and research enjoyed by the younger academic men of to-day. To them he sometimes appeared austere and even intolerant, but many grew later to know him as a sincere friend. His solid Edinburgh home meant much to him, and he felt very deeply the recent loss of his wife after a trying illness. He himself will be greatly missed.

L. DUDLEY STAMP

Mr. David Milne, C.I.E.

MR. DAVID MILNE, who died recently, was one of the fast-dwindling members of the Indian Agricultural Service, which was started about 1903 and the members of which by their devoted labours did so much to improve agriculture in India and from which she is now reaping the benefit.

Born in Scotland in 1876, Milne was educated in the University of Aberdeen, where he took his degree in science. His first appointment was to Egypt, where he was agricultural chemist to the Corporation of West Egypt, and when, no doubt, he made his first contact with cotton, a crop with which he was intimately concerned for the remainder of his career.

In 1907 he joined the Indian Agricultural Service and was posted to the Punjab as economic botanist, a post he held until 1921, when he became principal of the Lyallpur Agricultural College. In 1922, however, he was promoted to be director of agriculture, Punjab, and held this important post until his retirement in 1933, being made C.I.E.

The name of Milne will long be remembered in the Punjab and India for his work in selecting new types of long-staple cotton. The climate of the irrigated areas of the Punjab present certain peculiarities, and the type of plant has to be selected to meet these conditions. After the First World War, there was a shortage of long-staple cotton, and the demand for cotton of the Middling American standard, and even a little longer in staple, was strong both from the Bombay mills as well as from Lancashire. Prior to his arrival, attempts to introduce seed direct from the United States had met with little success, for these varieties failed to thrive under Punjab conditions, and although they obtained a premium on quality, they failed to find popular favour because their yields were very much smaller than the short-stapled Deehi, a native Indian type. By applying modern methods of plant breeding, Milne evolved new varieties of American upland-type cotton which not only withstood jassid and other pests but also gave yields approximating to those given by the native types. The first of these cottons was a variety called 4 F, and it was replaced by a variety with a somewhat longer staple, 284 F, and other selections followed. As a result of his work, American upland cottons of long staple came to be cultivated over very large areas in the Punjab and Sind and did much to meet the demand of the Indian mills.

Although most of his scientific work was applied to cotton, he found time to study other crops as well, and made a detailed study of the possibilities of cultivation of date palm in the Punjab. His "Handbook of Field and Garden Crops in the Punjab" also proved of great value in teaching establishments.

Milne became a member of the Indian Central Cotton Committee and was also on the Council for Agricultural Research in India from 1928 until his retirement in 1933.

G. EVANS

NEWS and VIEWS

Chemistry at King's College, Newcastle upon Tyne (University of Durham):

Prof. W. F. K. Wynne-Jones

ON the retirement of Prof. G. R. Clemo, who has been director of the Chemical Laboratories at King's College, Newcastle upon Tyne, since 1932, Prof. W. F. K. Wynne-Jones becomes professor of chemistry and head of the Chemistry Department. Prof. Wynne-Jones, who was appointed to the chair of physical chemistry in the College in 1947, has carried out distinguished work in the field of chemical kinetics (see *Nature*, 160, 291; 1947).

Organic Chemistry: Prof. G. R. Clemo, F.R.S.

PROF. G. R. CLEMO retires at the end of this session from the chair of organic chemistry at King's College, Newcastle upon Tyne, which he has occupied since 1925. Clemo received his early training at University College, Exeter, and, after a period as science master at Penzance, he went to the Queen's College, Oxford, to work under Dr. Chattaway. His experimental skill was used to the full during the First World War, when he worked in a team under Prof. W. H. Perkin on the synthesis of dyestuffs which were urgently needed because the industry had been allowed to lapse in Britain, whereas it was extensively developed in Germany. In the years immediately following the War he continued to work under Perkin and was a well-known figure in the Dyson Perrins Laboratories at Oxford. In 1924 Clemo was appointed director of the research laboratories of the British Dyestuffs Corporation at Manchester, a post which he relinquished on his appointment to the chair of organic chemistry at Armstrong College (now King's College, Newcastle upon Tyne). His tenure of the chair has been marked by considerable productivity and by the growth of the Department to its present high position in the chemical world. Clemo in his own work has been an outstanding disciple of Baeyer and Perkin, and, while his interests have ranged over the whole field of natural products, he has contributed particularly to an understanding of the lupin alkaloids. He and his associates have also synthesized anti-malarials related to quinine, and in recent years Clemo has been studying the little-known alkaloid tazettine isolated from snowdrops, and has directed his attention to the widespread black pigment, melanin. Throughout his career Clemo has been devoted to the laboratory bench, and has set an example of personal industry which has stimulated his associates.

Prof. F. S. Spring, F.R.S.

PROF. F. S. SPRING, who is to succeed Prof. Clemo, was educated at Waterloo Grammar School and in the University of Liverpool, where he began research work under Prof. I. M. Heilbron. In 1930 Spring went as assistant lecturer to the University of Manchester, and had attained the position of senior lecturer when he left in 1946 on his appointment as Freeland professor of chemistry in the Royal Technical College, Glasgow. In his association with Prof. Heilbron as pupil and collaborator, Spring carried out an extensive and an impressive study of the chemistry of the sterols. Since going to Glasgow, he has built up a flourishing school of organic chemistry which has made important contributions to the

chemistry of the steroid and triterpenoid groups of chemical substances. In this study they have succeeded in isolating triterpenoids of unusual structure from *Strychnos nux-vomica* and from opium. Spring's work has led him to close association with the medical aspects of organic chemistry, and he has been investigating possibilities in the synthesis of cortisone as well as the possible relationship of steroid metabolism to arthritis. Spring has shown himself a master of experimental method and an original investigator: his enthusiasm and energy combined with his clear insight into problems of organic chemistry ensure that the development of this subject will continue in Newcastle.

Directorship of the Bermuda Biological Station:

Dr. L. W. Hutchins

DR. LOUIS W. HUTCHINS has been forced by ill-health to retire from the directorship of the Bermuda Biological Station, in which capacity he has served since 1949. Dr. Hutchins is a graduate of Yale University, receiving his doctorate in zoology in 1941, and was Mary S. Muellhaupt Scholar at Ohio State University during 1941-42. He then became associated with the Woods Hole Oceanographic Institution in connexion with investigations being made for the United States Navy on the prevention of marine fouling, and he contributed several chapters to a monograph on "The Prevention of Marine Fouling", prepared by the Woods Hole Oceanographic Institution for the Navy. Dr. Hutchins is a specialist on the salt-water Bryozoa and has made important contributions to the interpretation of temperature zonation in geographical distribution. He is now an associate on the staff of the Woods Hole Oceanographic Institution.

The Bermuda Station was founded in 1901 by Dr. E. L. Mark, of Harvard University, for the scientific study of biology. When it was reorganized and incorporated in 1931, it received an endowment from the Rockefeller Foundation to permit it to function also as an oceanographic station, for which its location is admirable. Dr. Hutchins was well fitted to develop this part of its activities, and he immediately initiated a general oceanographic programme for working out the economy of the waters inside the fringing reefs and their relationships with the ocean water outside.

Dr. W. H. Sutcliffe, Jun.

DR. WILLIAM H. SUTCLIFFE, JUN., who has been appointed to succeed Dr. Hutchins at the Bermuda Biological Station, has served as staff biologist at the Station since 1951 and is consequently well acquainted with the local situation and the fauna of the islands. A native of Florida, he was educated at Emory University and at Duke University, where he was granted his doctor's degree in 1950 for studies in marine ecology. Prior to going to Bermuda, he worked at the Institute of Fisheries Research of the University of North Carolina, where he conducted research on zooplankton and on the commercially important shrimp of Carolina waters. At Bermuda he has been investigating the biology of the spiny lobster, *Panulirus guttatus*, on behalf of the Bermudan Government. He has published papers on the taxonomy of the calanoid copepods of North Carolina waters and on the breeding and migration of the spiny lobster. Dr. Sutcliffe brings to his task as director experience in the application of oceanography to fishery problems. His pre-

decessor organized an oceanic fisheries conference in Bermuda during 1951, at which the prospects for taking fish from the open and deep ocean—a difficult problem—were explored. An outcome of this was the provision by the Bermudan Government of a research vessel for ocean work, which should enable valuable fishery investigations to be undertaken.

Institution of Civil Engineers' Secretaryship: Mr. E. Graham Clark, C.B.E.

WHEN he retires this year on reaching the age of sixty-five, Mr. E. Graham Clark, secretary of the Institution of Civil Engineers, will have completed thirty-five years on the permanent staff of the Institution. A graduate of the University of Durham, he had spent four years as a pupil and assistant engineer before the First World War took him into the 50th (Northumbrian) Division, Territorial Forces. He was awarded the Military Cross, and on his return home in 1919 joined the staff of the Institution of Civil Engineers as chief technical assistant. He later became chief assistant to the secretary, Dr. H. H. Jeffcott. After a period as acting secretary in 1937, Mr. Clark was chosen to succeed him. Only those who have worked closely with Mr. Clark know how loyally and enthusiastically he has striven to advance the prestige and usefulness of the Institution. He leaves an Institution which has greatly developed in character and influence during his years of office. Before his time, there were no special divisions of the Institution, no Colonial Engineering Conference and no international associations of engineering societies. The local associations and the associate members of the Institution were not represented on the Council. Institution meetings were relatively few and the publications far less comprehensive than to-day. The bringing together of the three major engineering institutions of Britain, the Civils, the Mechanicals and the Electricals, to work in close collaboration has been one of Mr. Clark's noteworthy achievements. This rapprochement was soon followed by the formation of the Conference of Representatives from the Engineering Societies of Western Europe and the United States of America and the Conference of Engineering Institutions of the British Commonwealth. He has played a leading part both in their inception and in the conduct of their business. Mr. Clark was honoured for his services to engineering by being created C.B.E. in 1948, and by the award of an honorary M.Sc. of the University of Durham in 1953.

Mr. Alexander McDonald

IN succeeding Mr. Graham Clark as secretary of the Institution of Civil Engineers, Mr. Alexander McDonald will be undertaking a task which has no equal in service to the civil engineering profession. A graduate of the University of Edinburgh, he entered the Nigerian Engineering Service after practical training in Britain. At the age of fifty, Mr. McDonald has completed more than twenty-five years service in Nigeria and has risen to become the Inspector-General of Works—the head of the Public Works Department—a post which he has held with distinction during the past three years of active political change in that country. He brings to his new task a wide and varied experience of civil engineering ranging from water supply to airfield construction, and has studied highway engineering in the United States. He has contributed two papers to the Institution. He has always shown a keen

interest in the affairs of the Institution, and it was to satisfy his desire for the Institution to play a greater part in the life of the Colonial engineer that the Colonial Engineering Conference, now held biennially, was instituted; he was also the moving spirit in forming the West African Joint Branch of the three Institutions and is its first chairman.

Verband Deutscher Physikalischer Gesellschaften

WITH the close of hostilities in 1945 the Deutsche Physikalische Gesellschaft and the Deutsche Gesellschaft für Technische Physik ceased to function; later, in their place, there was founded the Verband Deutscher Physikalischer Gesellschaften, made up of the following five organizations: Physikalische Gesellschaft in Bayern, Physikalische Gesellschaft zu Berlin, Physikalische Gesellschaft Hessen-Mittelrhein, Nordwestdeutsche Physikalische Gesellschaft, and Physikalische Gesellschaft in Württemberg-Baden-Pfalz. At a meeting of the Verband in Innsbruck last September it was decided that amends should be made to all former members of the two original German physical societies whose names were removed, for political or other reasons, from the societies' rolls. There are many such persons, mostly living outside Germany, and an attempt has been made to get into touch with each one by letter and invite him to join the new organization. Unfortunately, in many cases it has not been possible to find out whether a particular person is still alive and, if so, what is his address; consequently, an open invitation is now being extended to all such victims of the Nazi persecution to join the Verband Deutscher Physikalischer Gesellschaften. All those interested or anyone who can give information regarding the whereabouts of any former member should write to the Verband at Scheffelstrasse 2, Heidelberg.

Visas to the United States for Scientific Workers

A NEW survey of the effects of the present immigration legislation in the United States on issuing visas to foreign scientific workers is now being made by the Federation of American Scientists. The Federation wishes to be informed, with as many details as possible, of any case during the past two years in which a scientific worker was refused a visa or in which the issue of his visa was delayed so long that his projected visit to the United States had to be cancelled. All information will be treated confidentially, and no information will be made public without the written consent of the person involved. The Federation is of the opinion that, if the present restrictive provisions on visas to the United States are to be amended, it will be necessary for the American public and Congress to be convinced of the inadequacy of the present law. This can be accomplished only by assembling information which shows the adverse effects of the present visa policy, and the co-operation of foreign scientists in this matter is therefore essential. Information should be sent to the Committee on Visa Problems, Federation of American Scientists, 1749 L Street, N.W., Washington 6, D.C.

M. and B. Laboratory Bulletin

THE first number of the *M. and B. Laboratory Bulletin*, a new venture of May and Baker, the well-known manufacturers of chemical reagents, was published in January, and further issues are promised from time to time (obtainable free from May and

Baker, Ltd., Dagenham, Essex). This number is a well-printed, well-illustrated, folio-sized booklet of twelve pages. The promoters intend to furnish information on apparatus, reagents and techniques from the work in their own laboratories, and on matters of interest to chemists generally. There is also a hint of forthcoming articles of wide cultural appeal by outside contributors. The editors have certainly in this first number set themselves a good model and produced a well-balanced journal. The articles, all by specialists, are entitled: petroleum; a gas-scrubbing tower; potassium borohydride; and in a secondary modern school. To complete the contents, there are four abstracts, illustrated and in smaller type, which deal with the contents of a bottle; a semi-micro ozonizer; the handling of sodium; and the distillation of mercury. Each of the articles is intended to be the first of a series discussing severally the industrial production of chemicals, industrial apparatus, new reagents, and the teaching of chemistry. The inclusion of the last feature shows that thought and vision have gone to the planning of the *Bulletin*. For, manifestly, the promoters realize that in these days of the industrial importance of chemistry its teaching is of vital significance.

Composite Wood

THE term 'composite wood' is not perhaps very widely known, and the editor of the new journal, *Composite Wood* (1, No. 1; October 1953. From 15 Beeson Road, New Forest P.O., Dehra Dun, U.P., India; price Rs. 2.8), has wisely set out on the title page his aims combined with a definition of the subject "... to promote the study and practice of the science and technology of composite wood (adhesives, plywood, laminated and other improved woods, building boards, etc.), and allied subjects". The journal is a welcome addition to the very few devoted entirely to the technical aspect of composite wood matters, and should be of value to the plywood and allied industries, which are now established in all parts of the world. The editor, Dr. D. Narayana-murti, is in charge of the Composite Wood Branch of the Forest Research Institute, Dehra Dun, and he and his associates have contributed extensively to this first number. The inclusion of an article by Dr. F. Kollmann, of Germany, however, indicates the international aims of the journal. In addition to four technical papers, under "Notes and News" are information on meetings of specialist societies, details of forthcoming specifications, and references to manufacturers' publications on new adhesives. The abstracts deal fully with papers bearing on composite wood, and, in the present issue, two books are reviewed. It is understood that the journal will be published every two or three months.

Maps of Africa South of the Sahara

A LIST of "Maps of Africa South of the Sahara" has been compiled and published by the Scientific Council for Africa South of the Sahara (Publication No. 4; pp. ii+122; from the Council, Bukuru, Belgian Congo, 1953; 15 francs). The list attempts to show the position in 1953. Historical maps have been excluded and so also have maps on a scale smaller than 1 : 1,000,000. Atlases are listed, but their contents are not detailed in broad terms. Maps of special subjects are included, such as geology, climate, vegetation and population. The mapping of Africa is advancing at a great rate, and there are few areas

that have no maps. Every entry gives the scale and source of publication.

Molluscan Adaptation

THE shell, mantle and organs in the mantle cavity of the characteristic *Pinna carnea* have been investigated in detail with special regard to their adaptation to the peculiar mode of life of this mollusc by C. M. Yonge (*Phil. Trans. Roy. Soc. Lond.*, B, No. 648; 1953). The shell, the shape of which recalls a partially opened fan, in the living animal is found with the pointed end embedded in the substratum with half its length, that is, considerably more than half its area, projecting freely upwards. This allows the inhalant current with its contained food particles to be drawn from clean water above the bottom and, conversely, the exhalant stream does not disturb the mud. However, standing upright and having free mantle lobes, the animal must be liable to a certain amount of silting, particularly when the surrounding mud is disturbed. We therefore find that it produces a strong exhalant current and that it has a special, powerfully ciliated waste canal wall provided with mucous glands, which plays an important part in removing silt and the pseudofeces. Such a projecting shell, incapable of withdrawing, is liable to injury and the mantle is highly retractable and not attached to the part of the shell that is exposed, so that it can be withdrawn to escape injury. It can quickly carry out repairs, but it follows from its limited attachment that the shell in its projecting area is composed of the prismatic layer only. This layer is, as usual, constituted by a concholin network impregnated with calcite crystals arranged in prisms. There is a very much higher proportion of organic matter than in most molluscs, so that the projecting part of the shell is flexible and hence less liable to breakage. The Pinnidae alone possess a pallial organ, a large unpaired tentacular structure, the function of which appears to be that of clearing away the broken pieces of shell.

Chemical Basis of Resistance to Fungal Attack

THE nature of the resistance of oats to *Ophiobolus graminis* has been investigated by E. M. Turner by testing the reactions of two varieties of the fungus to the sap (*J. Exp. Bot.*, 4, 264; 1953). The two varieties of the take-all fungus, *Ophiobolus graminis* and *O. graminis* var. *avenae*, show a differential reaction to sap extracted from oats; the type variety, which is incapable of causing a lasting infection of oats *in vivo*, is inhibited by the sap *in vitro*, whereas var. *avenae*, pathogenic to oats, can grow in the sap. The inhibitory action of the sap is not due to a lack of food material required by the fungus, but to a specific substance or toxin. The method used for assaying toxicity is described. The inhibitor is produced in considerable quantity in the leaves and stems of oats and in smaller quantity in the roots. It appears to accumulate mainly during the period of active growth and to be less active, or present in smaller concentration, in adult plants. It can be detected in the seminal roots throughout their existence, although during the first three weeks of growth *O. graminis* can invade the cells of the cortex. It is present in greater quantity in the crown roots, which are never penetrated. A similar inhibitor of *O. graminis* can be extracted from *Arrhenatherum elatius*, but not from other grasses which, both in the field and in pot experiments, appear to be equally resistant.

Rouelle and Chemistry In France

AN interesting paper in *Endeavour* (July 1953) by Dr. Douglas McKie deals with Guillaume-François Rouelle (1703-70), demonstrator in chemistry at the Jardin du Roi in Paris, and the teacher of Lavoisier and Diderot. He discusses a set of notes of Rouelle's lectures belonging to the Science Library of Clifton College, and there is a coloured reproduction of a miniature of Rouelle, also in Clifton College. Dr. McKie points out the important role which Rouelle took in the development of French chemistry; but in saying that it was he who introduced the phlogiston theory into France, Dr. McKie seems to overlook the account of the theory contained in a two-volume book 'Nouveau Cours de Chymie, suivant les Principes de Newton & de Sthall', published in Paris in 1723, at a time when, Dr. McKie says, Rouelle was still a student.

Watsonia: a Journal of British Botany

BEGINNING with the first part of Vol. 3 (published December 1953), *Watsonia, The Journal of the Botanical Society of the British Isles*, now appears in the format of most important scientific journals (obtainable from the Department of Botany, British Museum (Natural History), London; 7s. 6d. per part). The aim of this journal is to provide a medium for the publication of original work on the taxonomy and distribution of flowering plants, vascular cryptogams and charophytes in the British Isles. Included in the present part are contributions relating to *Montia fontana*, *Nuphar intermedia* (a presumed relict hybrid), regional variation in *Alnus glutinosa*, Arctic plants not yet found in Britain, the distribution of *Dryopteris Borreri*, and notes on *Carex flacca*.

Careers In Agricultural Research

A USEFUL pamphlet entitled "Careers in Agricultural Research—Training Grants, Studentships and Fellowships awarded by the Agricultural Research Council, 1954" has recently been issued by the Agricultural Research Council. There are openings for research workers in many of the twenty-six agricultural research institutes financed by the State. In addition, certain appointments in universities and other research institutions are financed by the Council; many of these are temporary in character, but are particularly attractive to the young worker who wishes to work under the personal guidance of a distinguished scientist. The pamphlet also gives useful information about the scientific staffs of the Council and of the State-aided agricultural research institutes, and about the advisory services. This year the Council is again offering two veterinary clinical fellowships to provide opportunities for suitably qualified veterinary clinicians and pathologists of Ph.D. standing to continue research for two or three years. The fellowships will be renewable annually up to a maximum of three years and will carry a stipend of £850 a year. In addition, the Council is continuing to offer a limited number of junior agricultural research fellowships, carrying a stipend of £630 a year, to research workers of outstanding ability; and a larger number of postgraduate training grants and research studentships in agricultural and veterinary science. Applications for awards should reach the Council by March 20. Further information and a copy of the pamphlet can be obtained on application to the Secretary, Agricultural Research Council, Cunard Building, 15 Regent Street, London, S.W.1.

Postgraduate Agricultural Scholarships

THE three Agricultural Departments of the United Kingdom have been allocated £625,000 over the next three years from the general allotment of Counterpart Funds given by the United States to Great Britain and other European countries for increasing productivity. It has now been announced that £25,000 of this sum will be devoted to postgraduate scholarships, the distribution being England and Wales, £15,000; Scotland, £5,000; and Northern Ireland, £5,000. In England and Wales the scholarships will be awarded in the following subjects, the qualifications required being considerably higher than for ordinary postgraduate scholarships: agricultural economics; farm management; estate management; and land economics and land use. Their value will be £400-£800 a year free of income tax plus all compulsory fees, authorized travelling expenses and a book allowance not exceeding £10 a year. Further information and application forms can be obtained from the Secretary, Ministry of Agriculture and Fisheries, 1-4 Cambridge Terrace, Regent's Park, London, N.W.1.

Australian and United Kingdom Postgraduate Research Studentships tenable in Australia

TO assist in the movement of scientists between various parts of the British Commonwealth, the Australian Commonwealth Scientific and Industrial Research Organization and the Department of Scientific and Industrial Research and the Agricultural Research Council of Great Britain are collaborating in an arrangement for providing a limited number of postgraduate research studentships tenable at Australian universities or other approved Australian research institutes. Under the arrangement, an allowance of £A800 a year and other approved expenses in Australia will be made by the Commonwealth Scientific and Industrial Research Organization, and the Department of Scientific and Industrial Research or the Agricultural Research Council, as may be appropriate, will pay travelling expenses to and from Australia. Candidates must be honours graduates in science or agriculture, and must be British subjects normally resident in the United Kingdom. The awards will be tenable for two full years in Australia. Full details regarding the conditions of the studentships are being made available to all departments of the natural sciences and agriculture in universities in the United Kingdom and to technical colleges and polytechnics.

Sixth Commonwealth Entomological Conference, London

THE sixth Commonwealth Entomological Conference will be held in London during July 7-16, and will be organized by the Commonwealth Institute of Entomology, London. Delegates to the Conference are being nominated by the Governments of the various countries of the British Commonwealth, including many of the Colonial Territories. In addition to the business meetings, which will be attended only by delegates, there will be open meetings on July 8, 9, 12, 13 and 15, at which subjects of wide interest to economic entomologists will be discussed. These open meetings will commence with short papers, read by invitation, the subjects being as follows: recent developments in the use of insecticides on field crops and against

locusts and tsetse flies; the effect of insecticides and other chemicals on the balance of animal populations; the development of resistance to insecticides; the estimation of losses from pests; the biological control of insects and weeds; the supply and training of insect taxonomists; pests of tropical cereal crops; developments in work on pests of stored products; problems of forest entomology; developments in termite research; recent developments in research and control of locusts and of tsetse flies. A report of the Conference will be published by the Commonwealth Institute of Entomology and will include reviews of the progress of economic entomology made by the Commonwealth countries during the six years elapsed since the last Conference. Programmes giving full details will be available about four weeks before the Conference from the Director, Commonwealth Institute of Entomology, 41 Queen's Gate, London, S.W.7, to whom all inquiries should be sent.

Development of the Mammalian Embryo: Cold Spring Harbor Symposium

THE nineteenth Cold Spring Harbor Symposium on Quantitative Biology will be held during June 7-14, when the topic of "The Mammalian Foetus—Physiological Aspects of Development" will be discussed. The primary function of the symposium will be to evaluate the principal morphological, physiological and biochemical factors that are essential for the immediate well-being and future development of the mammalian embryo. This will involve a consideration of hereditary-foetal and maternal-foetal relationships, as well as of the development and function of the membranes, decidua and trophoblast of the conceptus. Attention will be focused on the homeostatic factors that contribute to normal somatic and visceral development of the embryo to meet the requirements of living before, during and just after birth. Twenty-four of the participants will come from European countries, including Belgium, Finland, France, Great Britain, Ireland, Netherlands, Norway, Sweden and Switzerland. The Symposium is being sponsored by the Carnegie Corporation of New York, the National Science Foundation, and the Association for the Aid of Crippled Children. The programme and any further information can be obtained from the Biological Laboratory, Cold Spring Harbor, New York.

International Photobiological Congress In Amsterdam

THE Comité International de Photobiologie (C.I.P.), known before 1951 as the Comité International de la Lumière, will be holding an international congress in Amsterdam during August 23-28, 1954, organized by the Netherlands Committee on Photobiology. The aims of the Committee are the stimulation of scientific research in the physics, chemistry and climatology of ultra-violet, visible and infra-red radiations as they pertain to biology, and the study of the effects and applications of these radiations in biology and medicine. The congress will review the present state of knowledge in certain important fields of photobiological investigation, pure and applied, and will provide a forum for the presentation of new researches; to this end three symposia will be held, with the chairman shown, as follows: photoperiodism in plants and animals (Dr. R. van der Veen, Eindhoven); the effects of ultra-violet radiation on

genetic elements of cells (Dr. R. Latarjet, Paris); and the fundamental effects of light on the skin (Prof. James Hardy, Philadelphia). In addition, it is planned to have reports on photopathology, phototherapy and on methods for the measurement of radiation. The three languages of the Congress will be English, French and German. Persons wishing to attend the congress should write as soon as possible to the Secretariate Congress C.I.P., Radiologisch Laboratorium, Wilhelminagasthuis, Amsterdam.

European Congress on Clinical Chemistry

THE first European Congress on Clinical Chemistry will be held in Amsterdam during September 23-28 (Royal Institute for the Tropics, 63 Mauritskade, Amsterdam-O), under the auspices of the Commission on Clinical Chemistry of the International Union of Pure and Applied Chemistry, and will be organized by the Netherlands Society for Clinical Chemistry. The two leading subjects will be: isotopes in the clinico-chemical laboratory; and physical methods of measurement in connexion with clinico-chemical problems. These subjects will be presented in symposia, made up partly of lectures given by invited speakers and partly of free communications, for which a maximum of fifteen minutes will be allowed. Those who wish to read a communication should send in their papers, accompanied by a summary of 100-150 words, to the secretary of the Congress, Ir. O. Meulemans, Racineaan 17, Utrecht, before April 1. Excursions to various institutes and laboratories and also to places of interest in the Netherlands are being planned. The fee for the Congress is full members 25 florins (about £2 7s.) and those accompanying members 10 florins.

Announcements

PROF. J. K. CHARLESWORTH, Department of Geology, The Queen's University, Belfast, has been awarded the Neill Prize for 1951-53 of the Royal Society of Edinburgh for his work on the glaciology of Scotland and his other valuable contributions to geology.

THE American Association of Scientific Workers is to celebrate Prof. Albert Einstein's seventy-fifth birthday on March 14. The celebration is designed to emphasize his contributions as a great scientist, humanitarian and defender of human rights and liberties.

THE Royal Dutch-Shell Group of Oil Companies is offering a research studentship in geophysics of value £450 a year (£500 for married men) and tenable for two to three years at the University of Cambridge, which is open to men of any nationality less than twenty-seven years old. Further information can be obtained from Mr. B. C. Browne, Department of Geodesy and Geophysics, Downing Place, Cambridge, to whom application must be made by July 1.

Two Ramsay Memorial Fellowships, worth £400 a year plus a grant for expenses not exceeding £100 a year, are being offered for chemical research; they will normally be tenable for two years. One of the Fellowships will be limited to candidates educated in Glasgow. Further information can be obtained from the Joint Honorary Secretaries, Ramsay Memorial Fellowships Trust, University College, Gower Street, London, W.C.1, to whom application forms must be sent not later than April 21.

BRITISH IRON AND STEEL RESEARCH ASSOCIATION WORK AT SHEFFIELD LABORATORIES

THE laboratories of the British Iron and Steel Research Association in Sheffield, which have recently been opened, have been built to provide laboratory and plant facilities for three of the Association's five divisions—those concerned with steelmaking, metal-working and metallurgy.

They have been planned in part to overcome a difficulty met with in much industrial research and particularly in that connected with the iron and steel industry. This is the very great difference in scale between laboratory bench-work and industrial-plant operations, which tends to make experiment on operating plant extremely expensive and diminishes the value of much preliminary work.

In addition to the more usual research facilities and offices, therefore, there are at Sheffield two so-called 'plant laboratories' in which experiments not far removed from the scale of steelworks operations can be carried out. They contain, in particular, an electric arc furnace, a rolling mill, a forging press and a high-speed wire-drawing machine. The plant laboratories are single-story buildings of 10,000 sq. ft. and 4,000 sq. ft. floor area respectively. There is a third new building, a three-story main block of approximately 30,000 sq. ft. floor area. There are also four buildings which were previously on the site, one of which is occupied by the Cutlery Research Council, an independent body which makes use of the Association's central administrative services, and works in close liaison with the three divisions of the Association.

Steelmaking Division

The Steelmaking Division is naturally concerned particularly with fuel efficiency, and carries out many field-trials and observations on industrial furnaces. Fairly recent extensions concern the measurement of flame heating-power and its relationship to changes in furnace-operating conditions. This is an attempt to apply in steelworks practice the results of the work of the International Flame Radiation Committee on the experimental furnace at Ijmuiden.

One of the Ijmuiden results requiring further study is that steam reduces flame-radiating power, yet an increase in steam/oil ratio is known to give faster melting in many furnaces. This may be due to several combined effects; for example, increase of steam will increase the momentum of the jet, and may therefore increase the convective heat transfer, which is known to be very important during the melting-down stage.

Other field-work related to fuel efficiency is that concerned with the infiltration of cold air in open-hearth furnaces. Two techniques of measuring the air or gas flow in the flue system of such furnaces have been developed. The first was based on Pitot tube surveys across sections of the system, which proved not to be of general application because many furnaces have no suitable location for Pitot tube measurements. In the second technique, therefore, radon was injected into, and traced through, the system. This technique is applicable to all furnaces, and permits a much more detailed survey to be made of the flow in furnace systems, including leakages at valves. Investigations of flow are usually accompanied by temperature measurements of the preheated air supply. The many instruments such

as suction pyrometers, radon tracer and various calibration equipments needed for this field of work are kept at the Association's Sheffield laboratories ready for use at member firms' works.

Work carried out in the Sheffield laboratory itself includes a number of intensive studies on the chemical engineering aspects of mixing metals and slags. Experiments have been done on the rate of reaction between metal and slags using various methods of stirring. Some of the more spectacular of these involve breaking down the molten iron into very small droplets (1 mm. diameter and less), and allowing them to fall into the molten slag. In all such experiments the iron-slag mixtures were water-quenched within a minute or so after the additions of iron, and by carefully crushing the slags it was possible to extract the iron droplets, grade them into various size fractions and determine their sulphur contents. The results showed that it was possible to effect a high degree of desulphurization (80 per cent or more) in seconds of time provided a sufficient degree of slag/metal mixing could be achieved. However, the experience obtained suggested that atomization methods would be impractical on a large scale.

The Steelmaking Division has at the laboratories a 10-cwt. electric arc furnace of a design to facilitate experimental work. This is being used for, among other things, studies of the economics of this method of steelmaking with the view of possible extension of its field of usefulness. Many types of high-quality bulk steel which it would be technically advantageous to make in electric arc furnaces are only just beyond the economic borderline, and comparatively small improvements in electric furnace practice might bring them over. In particular, power and electrode consumption are being studied both on production furnaces and on the experimental furnace. The experimental furnace has a very large transformer for its size (500 kV. amp.), and the effects of high power inputs are being examined. The biggest effect so far found is, naturally, that of rate of power input during melting down on power consumed during this period, and in the Association's furnace about 20 per cent less power is required with an input-rate of 500 kV. amp. than with 250 kV. amp.

A further important purpose of the furnace is to provide molten steel for a variety of experiments, mainly on problems of casting. A commercial-scale continuous casting plant to the Association's design is now being built at a Sheffield works, and work continues on the many practical problems involved.

Mechanical Working Division

The Mechanical Working Division has a wide range of metal-forming and experimental plant housed in a fine, one-story building of 10,000 sq. ft. floor area. A 14-ft. four-high reversible cold-rolling mill is equipped to allow as wide a field of cold-rolling research as possible to be undertaken. Operating conditions have therefore been extended far beyond the normal production limits. At present the mill is equipped with a method of automatic gauge control developed by the Association on the basis of some years of work on the causes of gauge variation in rolled strip, in the course of which useful fundamental contributions to knowledge of the plastic behaviour

Metallurgy Division

of metals have been made. Continuous measurement by roll force meters of the separating force of the rolls indicates gauge variation; this is fed into a control circuit which immediately corrects variation either by altering the strip tension or the gap between the rolls. As an example of the potentialities of the method, a rundown of gauge of nearly 0.002 in. on 0.049 in. between 30 ft./min. and 250 ft./min. regularly occurred on an experimental 10-in. two-high mill without automatic control; with it, the entire strip was held to within ± 0.0001 in. at all speeds. The demonstration was repeated on a much larger scale by equipping a 56-in. wide four-stand cold reduction mill, one of the largest of such plants in Europe, with a similar type of control. It was found possible, even on this scale, to roll consistently at all speeds to far closer tolerances than are at present possible without automatic control.

After these trials and demonstrations, a period of intensive development is necessary, in which the Association's 14-in. experimental mill will play an important part. The best methods for development have yet to be decided, and there are other rolling variables, such as thermal expansion and bearing clearance, which may need to be considered and which threaten to increase the complexity of the equipment needed.

Other experimental metal-working plant includes a 200-ton capacity hydraulic forging press and a high-speed two-hole wire-drawing machine with a maximum finishing speed of 5,000 ft. per min. The press is being used to study the effect of forging strain on mechanical properties. Different tool-ratios and reduction-rates are being used, and attempts are being made to correlate the resulting mechanical properties within the material with the actual forging strains as determined from geometrically similar experiments using 'Plasticine'. It may then be possible to specify with more certainty the optimum forging reduction and the sequence of operations necessary to produce desired properties.

The wire-drawing machine is being used for examining problems of high-speed wire-drawing, in particular the limitations imposed by lubrication. The film thickness of the lubricant is being studied by measuring the electric resistance of the die-wire interface. This resistance is much larger than one would expect if the film were only a few molecules thick. Moreover, it is markedly dependent on speed. In one instance, the resistance increased from about 10 ohms per sq. cm. at 5 ft. per min. to about 50 ohms per sq. cm. at 50 ft. per min. with peaks exceeding 500 ohms per sq. cm. Experiments at speeds prevalent in industry are in progress and give a similar picture. Current investigations are also concerned with improved methods of applying the lubricant; for example, by electrodeposition from solution on to the moving wire. It is hoped to obtain in this manner a more consistent thickness of lubricant film and therefore a more uniform performance of the die.

The success of experimental research in metal-working depends to a large extent on the development of theory both to guide the choice of experiments and also to enable the results to be effectively interpreted. There is within the Mechanical Working Division a section concerned with theoretical plasticity, which has made useful contributions to the practical work. Exact and approximate plastic-rigid solutions have been shown by experiment to be a good guide to the behaviour of real metals.

The Metallurgy Division at Sheffield includes facilities for heat-treatment, general metallurgical examination, mechanical, magnetic and electrical testing and X-ray structural studies as well as for chemical, spectrographic and vacuum fusion analysis. The fatigue-testing laboratory and the high-frequency electric furnace, in which 56 lb. of metal may be melted and cast *in vacuo*, are of particular interest.

An important part of the work is concerned with researches on pure materials. Small variations in the amounts of residual elements found between different casts of a steel having a given nominal composition can have a large effect on its properties. Research concerned with the effects of composition on the properties of steels carried out on alloys made from pure materials provides valuable background information. As such research is expensive and cannot be undertaken by every industrial laboratory, it is particularly suitable for a research association. At present this work includes the study of the effects of nitrogen and carbon on the strain-ageing characteristics of pure iron, and the effect of impurities on the magnetic and electrical properties of pure silicon-iron sheet, while a study of the properties of alloys made from pure materials, and having compositions similar to the nominal compositions of commercial steels, is contemplated.

In the studies of silicon-iron sheet of the type used for transformer cores, the effect of small controlled amounts of nitrogen are being studied with the view of determining the indirect effect which nitrogen has through its influence on the crystallographic texture of the cold-rolled sheet, and the direct effect of nitrogen as an impurity. The variations in texture are being studied with a torque magnetometer which gives an indication of the anisotropy, and also by orthodox X-ray methods which give quantitative information about the texture. The magnetic properties of the silicon-iron are being studied by means of a standard instrument.

The fatigue laboratory is equipped with twelve fatigue-testing machines of the two-point loading rotating bending type, similar in design to those used by the Mechanical Engineering Research Organization and the National Physical Laboratory. The speed of the machines is controlled, and rates up to 5,000 r.p.m. are possible, at which speed the machines are clear of any resonance which might influence the results. Each of the twelve machines is therefore able to provide approximately 7,000,000 stress cycles every 24 hr.

The main programme is concerned with the systematic sampling of three commercial casts of steel, using some 3,000 test pieces, to gain information on likely variations within casts of steel and between different casts of steel of the same specification. Information is also sought on whether structural variations in the ingot give rise in the rolled or forged products to significant variations in fatigue properties, and if they do, whether these variations are more pronounced in some ingots of a cast of steel rather than in others. The programme takes into account the fact that it is now widely appreciated that such values as fatigue life, fatigue or endurance limit are not exact values but are, in fact, statistical in nature. It has therefore been planned in collaboration with the Association's operational research section.

BIOLOGICAL SPECIFICATION AND BIOLOGICAL STANDARDS IN THE BRITISH PHARMACOPOEIA, 1953*

By PROF. A. A. MILES, C.B.E.

Lister Institute, London, S.W.1

A NUMBER of reputable drugs in common use to-day have been fully explored by chemists and physicians, so that we know their chemical constitution, and, in many cases, can synthesize them. In a publication like the "British Pharmacopoeia, 1953", which specifies these drugs for public use, it is enough for most drugs to state the degrees of chemical purity required to ensure that the medical practitioner and the general public have medicines upon which they can rely. But there are a number of substances available for the prevention and cure of disease, usually obtained from animals or plants, which we recognize mainly by their biological activity, and although we know something of their chemistry we do not know enough to recognize an active preparation by chemical tests alone.

Some of these 'biologicals' may in time yield to chemical analysis, if they are small enough or simple enough in structure. It is significant that, of the substances in the "Pharmacopoeia" the molecular weight of which can be stated, only sixteen are greater than 500, and two greater than 1,000. We shall wait long for the chemistry of any active principle, not a polymer, that has a molecular weight much greater than 1,000. In the meantime, drugs like insulin and the antitoxic globulins with molecular weights in the tens and hundreds of thousands, and the various immunizing antigens and vaccines, are quite beyond chemical specification. Apart from tests of identity, the most important biological specifications that complete the inadequate chemical and physical specifications in the pharmacopoeial monographs are the potency requirements. Now biological potency is by definition a measure of activity in some biological systems. The system may be a whole animal, such as a cat; part of an animal, like a guinea pig uterus or a suspension of red blood cells; or a culture of bacteria. Whatever the system, our first idea of potency is the amount of a substance that does something observable to it. Since we cannot test the activity in the human subject, we have in all cases to make the assumption that the effect we measure in the biological system is an indication of the effect we want to produce in the human patient. Sometimes that assumption proves to be unjustified, because we are using the wrong biological system, or observing the wrong effect in the right system; but in most cases it has proved to be correct. Our next problem is to translate the effect we observe in the test system into a measure of the potency of the drug.

The estimation of potency as the amount of a substance that produces a defined response in a given biological system is subject to the notoriously high variability of such systems, including the day-to-day variability in one laboratory and variability between laboratories. The limits of error of such 'direct' estimates of potency can only be guessed, and the reliability of such guesses parallels our success in achieving a precise specification of the biological

test system—in most cases an impossibility. When we can make only very imprecise measures of potency, clearly we are in no position to specify a drug that is poisonous in an over-dose or endangers the success of the treatment in under-doses. Happily, in a number of substances the biological activity of which can be measured only by the direct method, over-dosage is not medically dangerous, and we can ensure that the patient gets enough by giving plenty. This state of affairs applies, for example, to the prophylactics used for the prevention of diphtheria. With a substance like insulin, where an over-dose may mean one kind of coma and an under-dose another kind, our methods must be precise. To substances like this it is possible to apply the more precise, 'orthodox' bioassay, in which the biological test system is in effect specified for each assay by testing a standard preparation of the drug in parallel with the unknown. Potency is then expressed in terms of the standard, not, as in the direct assay, in terms of an unstandardizable animal or other biological object. Biological standards may be used in this way when the active material can be preserved in a stable form, and when it is reasonable to assume that the active principle in the standard is homogeneous and similar to that in the material being assayed; and that the biological response observed is due to the substance the therapeutic action of which it is intended to exploit. In the "British Pharmacopoeia" the biological standards prescribed for use are either international standards maintained by the World Health Organization or, when there is no international standard, British standards established by the Medical Research Council.

Bioassay of a drug is sometimes called 'standardization'. The term, however, should be confined to the establishment of the standard preparation. Thus, diphtheria antitoxin was standardized once and for all when, in 1922, the International Standard for Diphtheria Antitoxin was set up and units of potency accepted. Assays of potency made in terms of this standard are parts of the 'specification' of therapeutic and other preparations of diphtheria antitoxin. We thus have a number of drugs the total specification of which, as in a pharmacopoeial monograph, include a biological specification in terms of a standard and, where no standard is available, some much less precise biological specifications in terms of a biological test object.

The bioassays in the "British Pharmacopoeia, 1953" are introduced by a section on the principles of modern bioassay. Most assays are now designed to yield answers such that the responses to graded doses of the standard and the test preparation can be transformed by suitable arithmetical manipulations into numerical values that will yield a linear response when plotted against the logarithm of the dose; and when both the standard and test preparation give substantially parallel linear dose-responses, the potency ratio is readily derived from the logarithmic distance between the two lines. Since the 1948 "Pharmacopoeia", assay methods and biological standards have been made available for aureomycin, scarlet fever antitoxin, globin zinc insulin, *d*-tubocurarine and dimercaprol.

Globin zinc insulin is interesting because, although it is used clinically as a 'delay' insulin, it is not possible to demonstrate any appreciable delay effect in rabbits without using prohibitive numbers of animals. Consequently, there is no test for delayed action in the "Pharmacopoeia".

* Substance of a paper before the Pharmaceutical Society, read on December 10, 1953.

The specification of immunological products leaves much to be desired from the formal point of view. In few of the antitoxins for which there are standards is an orthodox assay, with calculation of fiducial limits of error, prescribed; but the precision and accuracy that might be attained if better assays were defined are probably unnecessary. For a large group of substances—the living vaccinia virus which constitutes the smallpox vaccine, and the living suspension of B.C.G. (*Bacillus* of Calmette and Guérin) which is a tuberculosis vaccine—there are no biological standards; they are all assayed directly in laboratory animals, with the consequent risk of a highly variable result. With B.C.G. vaccine, the results of even the various direct assay and tests have only a retrospective interest, because they take three weeks to six months to complete and the vaccine keeps its potency only fourteen days after issue for use in man. The 'dead' vaccines—that is, bacterial suspensions of killed typhoid and paratyphoid bacilli, whooping cough bacilli, plague bacilli and so forth—are not assayed for potency at all. At present, reliance is placed on the selection of the right strain of microbe to start with, and its proper cultivation and treatment in the manufacture of the vaccine. In other words, the specification stresses the 'pedigree' of the finished product as well as its properties at the date of issue.

With the exception of thrombin, haemoglobin and fibrinogen, none of the human blood products in the "Pharmacopoeia" can be assayed biologically, or even specified in any precise way; but there are precautions to be taken in selecting the donor, whose blood will be the source of the various blood products—"Whole Blood", "Human Serum" or "Fibrinogen", and so forth—all of which are, on the face of it, very sketchily described.

These gaps in the specifications are, however, only apparent. It must be emphasized that all such pharmacopoeial substances—immunological and human blood products—for which the biological specification is superficially inadequate are under the control of the Therapeutic Substances Act. That is to say, they can be manufactured for sale only under licence from the Ministry of Health; it is consequently not enough that a vaccine should be prepared in such a way that it passes a biological test as laid down in the "Pharmacopoeia". Its control ends, not begins, with the test of the finished product. It has always been the policy of the Ministry of Health in applying the Therapeutic Substances Regulations, and of the Medical Research Council in advising on the research aspects of their application, to recognize that the control of these biological substances begins in the producing laboratory, so that all stages from the raw material to the finished product are in charge of expert staff who work so as to leave no loophole for variability so gross as to lead to unwanted results in the use of the drug.

The prescribed methods of control in the "Pharmacopoeia" are instructive in that they range from the simplest tests of activity in the animal to the most elaborate assays which in design and execution would satisfy the most meticulous biometrician. The differences necessarily reflect the differences in our current knowledge of these substances and how to handle them in the laboratory. Imperfection there must be, because we can often recognize and purify an active principle which it would be wrong to withhold from the practitioner of medicine until we

know exactly what it is. But it is comforting to reflect that no such substance is included in the "Pharmacopoeia" unless the imperfections in our knowledge have been removed at least so far as knowing the potentialities of the drug, both beneficial and dangerous. The biological specifications in the "Pharmacopoeia" ensure that we know well enough what amount of a drug will have no effect; what amount will have a beneficial effect; and when the second amount is exceeded, where the danger zone begins.

ALGAL PHYSIOLOGY AND BIOCHEMISTRY

IT has long been recognized that certain algae are particularly suitable as experimental material in the investigation of some of the classical problems of plant physiology and biochemistry. Valuable and extensive information about them has been accumulated, but it seems that concentration upon such species has resulted in inadequate appreciation of the variety of physiological behaviour and chemical activity which is to be found among the algae. A symposium on the physiology and biochemistry of this group of plants, in which the contributions were mainly concerned with species more familiar to marine and freshwater biologists than to most plant physiologists, is therefore of particular interest and an indication of increasing realization of the intrinsic interest of algae. Such a symposium, arranged by the British Phycological Society, was held under the chairmanship of Prof. W. H. Pearsall in the Botany Department of University College, London, on January 1.

In a paper on the physiology of algae other than *Chlorella*, Dr. G. E. Fogg directed attention to features in which certain species being investigated by the Unit for Algal Physiology at University College differ markedly from *Chlorella*, the genus of algae best known to the physiologist. *Monodus subterraneus*, a member of the Xanthophyceae, is morphologically the analogue of *Chlorella*, but unlike members of this genus cannot tolerate wide variation in the composition of the mineral medium in which it grows and appears to be an obligate phototroph. *Anabaena cylindrica*, a nitrogen-fixing blue-green alga, has proved particularly suitable for investigation of the metabolic role of molybdenum. Results recently obtained show that this trace element is not specifically concerned in nitrogen metabolism but that it exerts its effects via carbohydrate metabolism and that the symptoms of its deficiency can be annulled in *Anabaena* if a suitable intermediate such as fumarate is supplied. Although all algae so far examined from this point of view, including *Chlorella* sp., produce extracellular peptides to a greater or lesser extent, *Anabaena* is a particularly favourable organism for the study of this phenomenon. Formation of chemical complexes with toxic or nutrient substances by the extracellular polypeptide of this alga can in certain circumstances have important effects on growth of the organism. The variation in proportions of carbohydrate, fat and protein shown by *Chlorella* spp. according to the conditions under which they are grown is also to be found in other algae, although in *Tribonema aequale*, for example, the possible range appears to be more

restricted. Blue-green algae seem to be incapable of accumulating high proportions of fat, as do *Chlorella* spp., under conditions of nitrogen-deficiency. *Botryococcus braunii*, which possesses chlorophyll *b* and which must therefore be assigned to the Chlorophyceae, is remarkable in accumulating high proportions of unsaponifiable lipid.

Dr. L. Fowden (University College, London), in reviewing present knowledge of the amino-acids and proteins of algae, pointed out that although the early work on this subject represents a considerable technical achievement, analyses by modern methods such as paper chromatography are not only performed more rapidly but also afford much more reliable results. Study of free amino-acids has shown that in *Chlorella vulgaris*, at least, the pattern of their metabolism is similar to that in higher plants. Among the free amino-acids, glutamic and aspartic acids and alanine are present in highest concentration, and other amino-acids can be formed by transamination from these to appropriate keto-acids. There are particular amino-acids characteristic of certain groups; this affords another example of the correlation to be found between biochemistry and classification in the algae. Quantitative analyses of the amino-acids of the bulk proteins of several algae, including *Chlorella*, *Tribonema*, *Navicula* and *Anabaena*, have now been made and show that the same amino-acids are present in much the same proportions as in the green leaves of higher plants. Early reports that certain amino-acids are absent from the proteins of some groups of algae were based on results obtained with inadequate analytical techniques. The proportions of different amino-acids in the bulk proteins of *Chlorella vulgaris* do not change markedly during the growth of cultures. Nothing is known as yet of the individual proteins of algae; but study of them is beginning with attempts at their separation by electrophoretic methods.

A paper by M. R. Droop (Marine Station, Millport) was concerned with the biology of hamatochrome in *Haematococcus pluvialis*. The accumulation of this pigment, the principal constituent of which is the carotenoid astaxanthin, is known to be promoted by high light intensity, by the supply of acetate, or by nitrogen deficiency. These effects have been confirmed; but it has been found that hamatochrome is also formed when growth is limited by phosphate, nitrate being in excess. No hamatochrome appears while cell multiplication is going on; when growth has ceased, its accumulation is most rapid when both organic carbon and carbon dioxide are available and slowest when carbon is in short supply. The effect of organic carbon is independent of light. It seems, therefore, that the formation of hamatochrome is promoted by factors which inhibit cell division but not carbon assimilation. Superficially, hamatochrome appears to be a reserve product, but its utilization and its relations to starch and fat have not been investigated. The red *Haematococcus* which occurs naturally is in a non-dividing condition, the dense populations which are often met with appearing to be built up rapidly from large numbers of aplanospores.

The kinetics of growth of a marine unicellular alga, long known as *Nitzschia closterium* forma *minutissima* but of doubtful affinities, were described by Dr. O. P. Spencer (Marine Station, Bangor). This form, unlike most marine algae, is sufficiently robust for routine laboratory handling and has the further advantage that its growth may, under certain con-

ditions, be followed accurately by determination of the optical density of the culture. The alga undergoes a period of exponential growth following inoculation into fresh medium, but even under constant conditions irregularities sometimes occur in this phase. These irregularities disappear on repeated subculture in medium of the same composition, and appear to be connected with adaptation to altered phosphate concentration. A lag phase is observed following inoculation into fresh medium if the inoculum is taken from a culture in which maximum cell density has been reached. Unless a massive inoculum is used, a lag phase of about five hours is also observed if the parent culture was in the early exponential phase. This suggests that some factor excreted by the cells must reach a certain concentration in the medium before exponential growth can begin, and this idea is confirmed by the finding that there is no lag following inoculation from the early exponential phase into medium in which growth has already occurred and which has been enriched with phosphate and nitrate. These results were obtained with media in which nitrate was limiting; phosphate-deficient media may produce cells having a lag phase of the order of ninety hours. Relatively high concentrations of phosphate sometimes exert a lethal effect, a phenomenon that has been observed with certain other algae and which may make it advisable to use phosphate-poor media when bringing a species into culture for the first time.

The mechanism of the absorption of glucose by *Scenedesmus quadricauda* was considered in a paper by F. J. Taylor (Queen Mary College, London). In oxidative assimilation by this organism, one-sixth of the glucose taken up is oxidized, the remainder being synthesized to polysaccharide. The increase in oxygen uptake following addition of glucose is immediate, and the uptake of glucose remains linear with time. This last fact and the observation that oxygen is essential for glucose uptake suggest that the process is one of active absorption rather than one of simple diffusion. Various observations are consistent with the idea that this active absorption is effected by a phosphorylase situated on the cell surface. Thus, no free glucose has been detected inside the cells by chromatographic methods, and phloridzin, which is apparently a specific inhibitor for phosphorylases, inhibits glucose uptake without reducing the rate of endogenous respiration. The rate of uptake of glucose remains constant as its concentration is increased until, corresponding with plasmolysis, there is an abrupt rise. This may perhaps be due to the uncovering of further enzymatic groups in the plasma membrane as it parts from the cell wall. No marked effect of age of culture on rate of glucose uptake was observed. Light has been found to stimulate the process.

Demonstrations illustrated some of the techniques in use in University College, London, for the study of algae. These included culture apparatus for various purposes, the most elaborate being an apparatus for continuous culture of unicellular algae, in which constant conditions and cell density are maintained by electronic control. Numerous species of unicellular and filamentous algae, both freshwater and marine, were exhibited in small-scale culture together with large-scale cultures (36- and 10-litre respectively) of *Chlorella* and *Tribonema*. The preparation of cell-free homogenates of algae for protein analysis was demonstrated, and various cytological preparations of blue-green algae were also exhibited.

NEW ZEALAND DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH

ANNUAL REPORT FOR 1952-53

THE twenty-seventh annual report* of the Department of Scientific and Industrial Research, New Zealand, covers the year ended March 31, 1953. It includes the Minister's statement, the Secretary's report and reports from the several branches of the Department, as well as from the Cawthron Institute, the Commonwealth Agricultural Bureaux, the research associations, the Manufacturers' Research Committee and the university colleges to which grants were made by the Department. The Minister's statement, stressing the way in which, particularly in the primary industries, the Department is assisting to put the results of scientific effort into practical use more rapidly than ever, and the satisfactory extent to which the Department has succeeded in establishing effective collaboration with other bodies in dealing with economic scientific problems, suggests that it is now an appropriate time to review the basis upon which research associations are financed by industry and by the State.

The Secretary's report notes a reduction in staff during the year from 1,012 to 931, that in professional staff being from 402 to 374. There were also considerable reductions in capital charges, in purchases of equipment and supplies and in travelling expenses, but reductions were spread as widely as possible. A critical analysis of the Department's expenditure of £1,020,720 estimates that 26 per cent was on long-term applied research; 22 per cent on scientific services for other government departments; 17 per cent on research and services to primary industry; 10 per cent each for defence science and on administration, information service, etc.; 7 per cent on research and services to manufacturing industry; 5 per cent on research grants; and 3 per cent on grants to British Commonwealth and international scientific institutions. It is estimated that the expenditure on research, as distinct from services, is probably about 43 per cent, and, reviewing the results of this expenditure over the past twenty-seven years, the Secretary points out that grassland research has enabled New Zealand, by breeding new strains of pasture plants and studying their management and utilization, to attain front rank as a pasture country with an exceptionally high yield of meat, butterfat and wool per acre. The annual production of fodder has been largely increased, the season of grass growth being extended by at least two months. New methods have been used for combating such serious diseases as facial eczema and bloat, and a considerable export trade has been built up in pedigree grass and clover seeds.

Soil surveys of the whole of New Zealand have been completed, and on this basis areas of erosion, of deficiency in lime and phosphate, and of the occurrence of plant and animal deficiency diseases have been mapped and the foundation thus laid for the utilization of the Dominion's soil resources. The areas liable to bush sickness have been defined and are now being brought into successful production. Research into plant diseases has brought many of them under complete control and others have been

made amenable to spray treatment. The fruit-growing industry has been provided with sound methods for the control of fungal and bacterial diseases and of insect pests, and bunt and smut diseases of barley and wheat are now rare. Research in fruit transport has eliminated the serious losses which were common twenty-five years ago in shipments to the United Kingdom. The serious physiological disease of apples, known as corky core, has been traced to boron deficiency and is easily and cheaply remedied. The wheat industry has been provided with a series of varieties unsurpassed in yield and quality of flour and in marked contrast to the Tuscan variety which they have replaced. The two most serious insect pests of pastures, grass grub and grass caterpillars, have been brought under control economically, as well as the diamond back moth which in bad seasons inflicted losses of turnips, rape and cabbage estimated at tens of thousands of pounds; and methods have been found by which South African citrus fruit may be imported to New Zealand without risk of introducing serious insect pests.

Recent research has discovered the cause of the yellow-leaf disease threatening the phormium industry and has indicated remedial measures which have removed the worst threat. Research in the tobacco industry since 1920 has led to the area under this crop being doubled as well as the yield of leaf per acre. The linen-flax industry has been established on research carried out by the Agronomy Division at Lincoln, the fish-liver oil industry on the investigations of the Fats Research Laboratory into the vitamin content of New Zealand fish livers, and the agar industry on the seaweed researches of the Botany Division and the Dominion Laboratory. These and other advances due to the research activities of the Department have afforded savings in any one year that would repay the whole of the State expenditure of nearly £8 millions on the Department during the past twenty-seven years.

The Secretary points out that so far no agreement has been reached regarding an adequate organization for the scientific problems of the building industry: in the Department's view, such an organization should be capable of adapting advances in building research institutions overseas to the special conditions of New Zealand; of undertaking research into New Zealand building problems and of disseminating knowledge to the industry. Progressive improvement in accommodation in many branches of the Department is recorded, including new premises for a section of the Geological Survey and for the Geophysics Division. The removal in the near future of the Botany Division headquarters to Christchurch should relieve the serious overcrowding in this Division of many years past.

Outstanding economic achievements of the year include savings estimated at £30,000 to Auckland tomato growers through the elimination of *Botrytis* disease by incorporation of a special fungicide in the hormone sprays used to induce setting of the fruit from early flower trusses. Investigations with the use of hormone sprays have now indicated that some 70 per cent of the cost of thinning apples in Hawke's Bay orchards can be avoided, with savings estimated at £20,000 annually, while in the fruit-growing districts of Central Otago treatment of pears, peaches and nectarines with zinc salts has checked die-back and restored normal vigour. Investigations on frost injury to fruit trees by facilitating more reliable pre-

* New Zealand. Twenty-seventh Annual Report of the Department of Scientific and Industrial Research. Pp. 108. (Wellington: Government Printer, 1953.)

diction of dangerous frosts has offered operating economies in fuel and labour. The Crop Research Division has produced strains of Blue Prussian and Greenfeast peas of proved resistance to wilt diseases, thus permitting higher yields and the more frequent use of peas in cropping rotation.

Tests in ground infested with black root-rot disease indicate that two varieties of tobacco introduced from the United States give yields higher by more than 500 lb. of leaf per acre, thus enabling tobacco to be grown profitably on areas abandoned on account of infestation by root-rot. Inoculation of the soil with methyl bromide has been shown to be as effective as steam sterilization for control of weeds in tobacco seedling beds, and the application of maleic hydrazide when the tops are removed eliminates all subsequent labour in the removal of lateral shoots. A considerable measure of control of stone fruit blast has been obtained by the Plant Diseases Division with the antibiotic streptomycin; nodule bacterial work in the same Division has produced a strain that promotes rapid establishment of clover in the raw pumice soils of the Wairakei-Tampo area, and complete control of thrips on onions has been obtained with DDT spray applied as an emulsion. The headnut disease and cutworm pests, which have been making serious inroads on the yields of maize in Poverty Bay, have been brought under control by means of a heavy dressing of fungicide in which an insecticide that deals with the cutworms is incorporated.

By a simple modification of the diffusion process of treating timber with boric acid, in which the green sawn timber is passed through a bath or spray of concentrated boric acid/borax solution and then held in block-stacks for a specified period, an inexpensive method of treatment has been evolved which was being tested on a semi-commercial scale. Promising results in breeding a new improved type of perennial ryegrass have been obtained in first-generation hybrids from perennial and short-rotation ryegrass, and the establishment of a well-balanced pasture-sward during the initially difficult stages has been facilitated by halving the amount of grass seed in an ordinary pasture mixture. At the Te Awa hill station the carrying capacity of pastures was increased to four ewes per acre compared with one wether a few years ago. Investigations on the control of grass grub and perina, which cause losses estimated at £6 millions annually, are continuing; but meanwhile the Entomological Research Station's recommendations for a DDT treatment costing less than £1 an acre has been substantiated.

Detailed soil surveys of the Gisborne Plains, Foxton Sands, Canterbury Plains and Downlands and the Heathcote Valley horticultural areas, and detailed geological and geophysical surveys of the Wairakei and Te Teko geothermal areas were completed during the year. Surveys were being extended northwards to the Waitapu area, and the use of the steam resources now being tapped was under consideration for the production of heavy water. The Department was also associated with the scientific aspects of the completely successful shipment of chilled beef, the first since pre-war years, by the New Zealand Meat Producers' Board to London on the *Dominion Monarch*. Various sections of the Department gave valuable assistance to several aspects of the work on the Maraetai hydroelectric dam, including stress and vibration measurements, and advice on paints and their protection; a special

feature was the examination by the gamma-ray equipment of the Dominion Physical Laboratory of all welds within the metal of the penstock controls and the location of flaws. In consequence, repairs to the penstock equipment were made in New Zealand, and the dam was brought into operation several months earlier than scheduled. The five industrial research associations of the Department all had successful years, and the Manufacturers' Research Committee gave special attention to the organization of trade research groups within the Auckland Industrial Development Laboratories and the Canterbury College Industrial Development Department so as to provide scientific assistance to manufacturing industries too small to form research associations.

ROYAL OBSERVATORY, CAPE OF GOOD HOPE

REPORT FOR 1952

THE report of the Royal Observatory, Cape of Good Hope*, for 1952, which has recently become available, shows that it was "a reasonably satisfactory" year for the Observatory. The weather, from the point of view of observing, was well above average during the first part of the winter, and good progress was made with the observing programme both at the Cape and at Pretoria. It was very satisfactory that the H-region zero-point programme was completed in a year, thus providing the material for rounding off the first half of the standard magnitude programme on which the Observatory has been engaged for a long time.

As stated in the report for 1951, arrangements were made for an examination of the declination axis of the Victoria telescope, in consequence of which it was out of action during a great part of 1952. Temporary repairs were not satisfactory, the motion of the telescope being still very stiff, and it was decided to fit modern roller and thrust bearings. This was not completed before January 1953; but it was possible to use the instrument for short periods between the various stages. The motion of the telescope is now quite smooth and easy, but it was used on only 63 nights during the whole year as compared with 177 nights in 1951. The opportunity was taken during the periods when the instrument was out of action to remove from the pier the old and massive weight-driven clock which was superseded in 1850 by a comparatively small electric synchronous motor, and at the same time to renew much of the electric wiring and to fit a new slow-motion motor. The tube of the 24-in. telescope was shortened by three inches in preparation for the fitting of the new lens cell recently made by the firm of Cox, Hargreaves and Thomson.

The astrographic refractor was used on 178 nights—32 more than during the previous year—in spite of the fact that it was out of commission for about three weeks in October and November in connexion with the remounting of the photometric cameras. Since their return from Cambridge, they have been adapted to use standard 16 cm. x 16 cm. plate-holders and have been fitted with new exposing-shutters working in front of the lenses and with an extra long dew-cap fitted with internal diaphragms to keep out

* Report of Her Majesty's Astronomer at the Cape of Good Hope to the Secretary of the Admiralty for the year 1952. Pp. 16. (Cape of Good Hope: Royal Observatory, 1952.)

scattered sky light. Although the instrument behaves fairly well, its drive and clamping mechanism need a thorough overhaul; the dome does not turn very freely, and the axles and bearings of the wheels carrying it are badly worn and will soon require renewing. The 7-in. telescope, now that the "Bright Star Programme" is finished, is used for observing occultations, and also by Mr. W. P. Hirst, a local amateur, for the micrometric measurement of double stars; Mr. A. G. F. Morrisby also uses it for observing variable stars. The 6-in. telescope, still utilized by visitors and for observing occultations, has been used regularly by Mr. R. P. de Kock for observing long-period variable stars. The Tower telescope and the photoheliograph, as described in the 1951 report, continue to be used, the first for observing occultations and variable stars, and the second for taking photographs—two each day—of the sun. A new photoelectric photometer, which was built during 1952 and used for a time on the Victoria telescope, has been transferred to the astrographic telescope to replace the old and rather inefficient photometer that was built originally for the 7-in. telescope; this new photometer will be used for the "Bright Star Programme" already referred to.

Nearly half the report is included under the heading "Observations and Reductions", and comprises: meridian observations, photographic star positions and proper motions, the parallax programme, Radcliffe section, stellar photometry, photoheliograph, occultations and variable stars. Under each of these, full accounts are given of the progress during the year under consideration. In the section on stellar photometry, reference is made to the photometric cameras, which were not mounted on the astrographic refractor until November 1952, and were brought into use in December. An outline of the two short programmes for this instrument is given, the second of which is required to complete the work done at the University of Cambridge Observatories.

A reorganization of the time service and clock installation was begun in August; but much detailed work still remains to be done, although the major changes were completed by the end of 1952. All the telephone cables in the grounds have been completely renewed by the G.P.O., to whose "remarkable speed, efficiency and close cooperation throughout, the Observatory is deeply indebted", in the words of the director. The Observatory keeps a limited stock of chronometers and watches for issue to H.M. ships; in 1952 nine were issued and ten received. Meteorological work proceeded on the usual lines, continuous records being obtained of barometric pressure, temperature, humidity, wind direction and wind velocity on self-registering instruments.

Towards the end of the report reference is made to the jubilee meeting of the South African Association for the Advancement of Science, which was held in July and which brought a number of distinguished scientists to Cape Town. After the meeting, Prof. J. H. Oort gave a popular lecture under the auspices of the Board of Extra-Mural Studies of the University of Cape Town, and so great was the popular response to this lecture that, by request of the University, Dr. D. S. Evans gave a series of six evening lectures on modern astronomical problems, which were all very well attended. Earlier in the year an astronomical exhibit, organized by Dr. Evans, was shown in the Hall of Science at the van Riebeeck Festival Fair.

It is satisfactory to know that, in addition to the regular visiting days and the opening of the Observatory for inspection one afternoon a month, the 5-in. and 6-in. telescopes have been placed at the disposal of the Cape Centre of the Astronomical Society of South Africa for the entertainment of visitors. These evenings have proved so popular that there has always been a long waiting list for the admission permits.

EUROPEAN TIMBER TRENDS AND STATISTICS

IN two United Nations publications, "European Timber Trends and Prospects"* and "European Timber Statistics, 1913-1950"†, the Food and Agriculture Organization of the United Nations has summarized information collected jointly by it and the Timber Committee of the Economic Commission of Europe; the second publication arises more or less out of the investigations contained in the first.

In the autumn of 1947, when the Timber Committee of the Economic Commission of Europe was first established, its purpose was to help European governments to overcome, through concerted action, the acute timber shortage which was hampering European reconstruction. To a certain extent success was achieved, despite the temporary disappearance of the U.S.S.R. as a large source of soft-wood supplies and without aggravating Europe's dollar deficit through continuous heavy imports of North American timber. By 1949 the temporary equilibrium reached was precarious and obviously unstable, and war restrictions in the consumption of timber and paper were still in force. But the questions still remained of whether or not Europe was still faced with a timber shortage, and how would supply and demand of forest products develop over a longer span of years. The Committee therefore undertook a study of European timber production, consumption and trade, primarily to find answers to these questions, and its findings are jointly summarized in "European Timber Trends and Prospects", which is a monumental piece of research work. The resulting beliefs appear to be that by 1960 Europe may be deficient in timber unless she increases her own production by a "dynamic forest policy" of reforestation and so forth, or imports larger amounts from North America and the tropical forests. It is open to doubt, taking into consideration the considerable period of time it takes trees to reach timber size, whether long forecasts are possible.

In the accompanying volume on "European Timber Statistics, 1913-1950" the periods covering the war years 1914-19 and 1939-45 have been excluded owing to the lack of adequate statistical information about them. This may seem to lessen the value of the inquiry somewhat since excessive fellings were made in the forests during the two World Wars, fellings which reduced subsequent consumption for a number of years. The volume is divided into three sets of tables, dealing respectively with production, trade

* *European Timber Trends and Prospects: a Study prepared jointly by the Secretariats of the Food and Agriculture Organization of the United Nations and the United Nations Economic Commission for Europe.* Pp. xvi+315. (Geneva: U.N.(F.A.O.); London: H.M.S.O., 1953.) 14 Swiss fr., 25s. or 3.50 dollars.

† *European Timber Statistics, 1913-1950: Statistiques Européennes du Bois, 1913-1950.* Pp. v+168. (Geneva: U.N.(F.A.O.); London: H.M.S.O., 1953.) 7 Swiss fr., 12s. 6d., or 1.75 dollars.

and consumption. It is stated that the object of the investigation is an attempt to fill a need felt by the majority of those entrusted with the role of wood in the European economy or who have tried to grapple with the timber problem on a European scale. For the first time, it is claimed, an attempt has been made to arrive at figures for trade and production in wood and its products for every European country, and to bring them together in the form of a convenient reference. This aim appears to have been usefully achieved. The volume has an increased value as it is in both English and French, the former on the left-hand pages and the latter on the right—a most effective method of increasing its utility.

E. P. STABBING

PARAMAGNETIC RESONANCE IN NEUTRON-IRRADIATED DIAMOND AND SMOKY QUARTZ

By DR. J. H. E. GRIFFITHS, J. OWEN and I. M. WARD

Clarendon Laboratory, Oxford

THE nature of lattice defects in neutron-irradiated diamond is a problem of current interest. These defects are known to cause changes in some of the physical properties¹ and give rise to a paramagnetic absorption spectrum. We have measured this spectrum in the temperature-range 20°–290° K., using wave-lengths of 1.2 and 3.1 cm. There are many closely spaced lines, of which two main types can be distinguished.

(a) There is an isotropic absorption line with spectroscopic splitting factor $g = 2.0028 \pm 0.0005$. Both the intensity and width increase with duration of irradiation, but are reduced after the diamond has been heated to about 1,000° C. (The intensity of the coloration produced by the irradiation varies in a similar way.) The line width, which after long irradiation is of the order of 100 gauss, decreases with temperature, being approximately half as big at 90° K. as at 290° K. This type of absorption line has also been observed in diamonds coloured by electron irradiation.

(b) There is an anisotropic spectrum consisting of lines symmetrically arranged about the type (a) line, and of the order a hundred times smaller in intensity. The intensity does not appear to be affected after heating to 1,000° C., and the line width is independent of temperature, being of the order of 5 gauss. This structure has been investigated in several Type 1 and Type 2 diamonds where the large central line had been reduced by heating. It is found that the positions in the spectrum of the most intense twelve of these anisotropic lines are identical in all the specimens that we have examined. They appear to arise from paramagnetic units in the crystal with electronic spin $S = 1$, the spin-levels being separated into a doublet and a singlet (separation $D = 0.010$ cm.⁻¹) by a crystalline field of nearly axial symmetry. This axis is found to be parallel to one of the six edges of the fundamental carbon tetrahedron of the diamond lattice, so that there are six differently oriented units present, each giving two lines in the spectrum (see Fig. 1). The mean spectroscopic splitting factor is $g = 2.0027 \pm 0.0005$, and has a very small anisotropy given by $g_{\perp}/g_{\parallel} = 1.00035 \pm$

Fig. 1. Spectrum from an irradiated diamond with magnetic field H parallel to $[111]$. A , central type (a) line (reduced by heating); B and B' , lines from one unit with axis parallel to H (that is, parallel to $[111]$); C and C' , lines from one unit with axis perpendicular to H ; D and D' , superimposed lines from four units with axes inclined at 60° to H .

0.00005 . For a general direction of the magnetic field the positions of the lines from each unit are given by the usual spin Hamiltonian $\mathcal{H} = \beta H \cdot g S + DS^2$, the constants having the values given above. Apart from these twelve lines, other smaller lines are also present, the intensities and positions of which in the spectrum are not found to be the same in all specimens.

A preliminary theoretical investigation of the magnetic properties of neutron-irradiated diamond, in which it is assumed that carbon atoms are knocked into interstitial positions leaving vacancies in the lattice, has been made by Pryce². Although it is too early to give any detailed interpretation of the spectrum described above, a tentative explanation which would give the correct spins of $S = 1$ and the particular axes of distortion is that this spectrum arises from interstitial carbon atoms linked together in pairs.

The centres which are produced in quartz by X-irradiation, giving rise to the well-known smoky colour, appear to be of a different kind from those in diamond, and have been thought for some time to be connected with the presence of impurity atoms in the silica lattice (see, for example, Brown and Thomas³). We have investigated the paramagnetic resonance in irradiated natural crystalline quartz and have found that a few hours irradiation by either neutrons, electrons or X-rays gives rise to the same spectrum. Prolonged irradiation by neutrons gives rise to additional absorption lines which will not be discussed here. For quartz irradiated by X-rays, it appears that the intensity of paramagnetic absorption is directly proportional to the coloration produced; the lines are completely removed by heating the quartz to 350° C. The spectrum is also found in synthetic quartz, but is much reduced in intensity.

Measurements using wave-lengths of 1.2 and 3.1 cm. have been made at 90° K., the lines being very much broader at higher temperatures. The results indicate that there are six types of paramagnetic unit, each with electronic spin $S = \frac{1}{2}$ and the same principal g -values ($g_{\parallel} = 2.06 \pm 0.005$; $g_{\perp} = 2.00 \pm 0.005$), but with differently oriented axes of magnetic symmetry. Each of the six absorption lines appears to be subdivided into six lines of roughly equal intensity with an overall separation of about 28 gauss at both wave-lengths (see Fig. 2). It is possible that this is a hyperfine structure, which suggests that the magnetic centres involve electrons,

Fig. 2. Part of spectrum at 1.2 cm. from smoky quartz including four of the six blocks of absorption lines. A and D, separate blocks showing the subdivision into six lines. B and C, two blocks with their centres displaced by one 'hyperfine' space.

moving in orbits closely associated with foreign atoms in the lattice, which have nuclear spin $I = 5/2$. The most likely impurity elements satisfying this interpretation are aluminium-27, manganese-55 and iodine-127, and of these aluminium is the most probable.

It is hoped to test this tentative explanation of the spectrum by measuring synthetic quartz into which known impurities have been introduced.

We would like to thank the Diamond Corporation, the Physics Department, University of Reading, the General Electric Company and the Atomic Energy Research Establishment, Harwell, for the loan and irradiation of specimens, and also Dr. A. H. Cooke, who first reported to us the presence of resonance lines in diamonds. [Dec. 18.]

EXPERIMENTAL INDUCTION OF BUDS FROM FERN LEAF PRIMORDIA

By ELIZABETH G. CUTTER

Department of Cryptogamic Botany, University of Manchester

RECENT comparative and experimental studies of leaf morphology have aroused a renewed interest in the relationship between leaves and buds. In the fern *Dryopteris aristata*, Wardlaw^{1,2} has shown that bud and leaf primordia are histologically identical, and that buds may be caused to develop at presumptive leaf positions when these are isolated from the shoot apex by a tangential incision. Similar preliminary experiments^{3,4} on the isolation of young emergent leaf primordia resulted in the development of awl-shaped leaves of limited growth and approximately radial symmetry, with associated axillary buds. Further experiments reported below have shown that under certain conditions it is possible to cause such leaf primordia also to develop as buds. (Following the terminology of Snow and Snow⁵, leaf primordia visible at the time of the operation will be called P_1 , P_2 , etc., P_1 being the youngest; primordia which were initially invisible but which developed during the course of the experiment will be called I_1 , I_2 , etc., I_1 being the first to arise.)

Leaf primordia of *Dryopteris aristata* were isolated from the shoot apex and adjacent primordia by four

fairly deep incisions. The isolated plugs were rectangular in shape and were relatively large; the majority of the plugs were elongated in a direction tangential to the shoot apex (Fig. 1A), but a few were elongated radially (Fig. 1B). These operations were carried out on primordia P_1 - P_4 over a period of ten months, from March to December 1953, and have resulted always in the development either of a bud or of a normal, dorsiventral, circinate leaf primordium. The results of the experiments are presented in Table 1. It was found also that, as in the case of Wardlaw's^{1,2} experiments on the I_1 presumptive position, isolation of the primordium from the shoot apex by a single tangential incision was sufficient to cause its development as a shoot bud. Notwithstanding the marked seasonal metabolic changes known to occur⁶ in the apex of *D. aristata*, neither the season of its collection nor the growth-rate of the apex had any effect on the development of the isolated leaf primordia.

Table 1. DEVELOPMENTAL ANALYSIS OF EXPERIMENTAL ISOLATIONS OF LEAF PRIMORDIA

Primordium isolated	Total No. of viable isolations	No. which developed as buds	No. which developed as leaves	No. which developed as leaves, or moribund leaves, with associated axillary buds
P_1	120	111	9	—
P_2	27	20	6	1
P_3	10	2	7	1
P_4	7	—	5	2

It is clear from these results that the youngest three leaf primordia, at least, are capable of development as buds if they are isolated from the influence of the shoot apex. While Table 1 gives a reliable indication of the ratio of buds to leaves which may be expected from isolations of P_1 , in many cases the examples of P_2 and P_3 were chosen because their relatively flat appearance indicated that they might be capable of development as buds. The results for P_2 and P_3 , therefore, do not give a reliable estimate of the proportion of buds to be expected from random isolations of these primordia.

From Table 2 it is evident that leaf primordia isolated at a late stage of the plastochrone yield a higher proportion of leaves than those isolated at an earlier stage. Careful observation of leaf ontogeny has shown that the distinction can be rendered more precise. A leaf primordium arises from the outgrowth of a group of equal prism-shaped cells of the apical meristem⁴; afterwards one of these cells, near the centre of the locus of growth, enlarges and grows

Fig. 1

Table 2. THE EFFECT OF THE STAGE OF THE PLASTOCHLONAL ATTAINED AT THE TIME OF ISOLATION ON THE SUBSEQUENT DEVELOPMENT OF ISOLATED P_1 PRIMORDIA

Stage of plastochlone	Total No. of viable isolations	No. which developed as buds	No. which developed as leaves	Per cent buds	Per cent leaves
Early	87	36	1	97.8	2.7
Middle	53	56	2	96.6	3.4
Late	25	19	6	76.0	24.0

out, taking precedence over the other cells. Ultimately this cell becomes very much enlarged, and its lateral walls become convex; at this stage it is recognizable as the characteristic lenticular apical cell of the leaf of this species. Before a single cell has visibly taken precedence over the other cells of the primordium and has grown out from the surrounding tissue, a primordium is capable of development as a bud, but after a single cell has become dominant and is beginning to become lenticular in shape, the primordium is no longer able to develop as a bud and, under the conditions of these experiments, will develop as a normal, dorsiventral leaf primordium. The stage at which a primordium attains this condition is variable in different apices; this explains how some primordia are still capable of developing as buds at as late a stage as P_2 . This has been confirmed by anatomical investigation. There must therefore be a close temporal relationship in this species between the irreversible physiological changes which impose upon a primordium dorsiventrality and a capacity for rapid but ultimately limited growth, and the formation of its apical cell. Such a relationship renders it possible to predict with a high degree of certainty which leaf primordia are capable of development as shoot buds under the prevailing experimental conditions.

Attempts were made to mark the centre, or, where visible, the apical cell of the primordium at the time of isolation with a free-flowing brand of Indian ink, applied with a small paint brush from which the majority of the bristles had been excised. No toxic effects of the ink were observed. Due to technical difficulties, it was not always found possible accurately to mark the central cell of the leaf primordium, and any initial discrepancy between the mark and the centre of the primordium became magnified as a result of growth and cell division. It was invariably found, however, that the ink mark occupied the same position relative to the apex of the induced bud as initially it had done relative to the apex of the leaf primordium. It therefore seems certain that the apex of the isolated leaf primordium does give rise to the apex of the bud.

The first leaf primordium of the induced buds always arose on the longest axis of the isolated plug, and in cases where the primordium was symmetrically situated on the plug two leaf primordia frequently arose almost contemporaneously, approximately opposite to one another. On plugs of the type illustrated in Fig. 1A, the first leaf primordium arose more frequently on the P_1 side of the plug than on the P_2 side; that is, on the side where there is slightly more space, since the isolated P_1 primordium is situated slightly closer to P_2 than to P_1 . Further experiments are necessary to establish the underlying cause. Normal spiral phyllotaxis usually was not established until after the inception of at least six leaf primordia; this is in agreement with observations on seedling apices of various angiosperms^{1,2}.

The vascular system of the induced buds was solenostelic; that of isolated primordia which developed as leaves was solenostelic at the base with normal leaf vascular structure distally^{3,4}. No vertical contact was ever made with components of the shoot stele; this is probably the reason for the ultimately rather limited growth of both induced buds and isolated leaves.

It appears that the different results obtained in earlier experiments on the isolation of leaf primordia were due to a difference in the position of the cuts, which were made as close to the primordium as possible⁵. Spatial and nutritional effects are still under investigation and have not yet been fully considered. It will be of interest also to determine the exact depth of incision which is necessary to permit development of the primordium as a bud.

From these experiments and those of Wardlaw^{1,2} it is apparent that, in *D. aristata*, leaf primordia are initially capable of development either as leaves or as buds, depending on the conditions operative upon them. This provides evidence against the existence of specific leaf- and bud-forming substances. Under normal conditions the primordia develop as leaves, determinate organs of dorsiventral symmetry and rapid growth, but it is possible to change their destiny by isolating them from some influence of the subtending shoot apex at a sufficiently early stage. Sussex⁶ was able to induce centric leaves in the potato by isolating the I_1 presumptive position from the shoot apex, and leaves of radial symmetry have been observed in the course of other experiments⁷⁻¹¹, always associated with either destruction or attenuation of the shoot apex. From plants of *Oenothera lamarckiana* which had been maintained under unfavourable conditions after destruction of the shoot apex, Lang⁸ obtained leaves bearing lateral and terminal buds, in addition to cylindrical organs, and leaves which gave rise apocarpously to prothalli at their tips. In some cases the tip of the leaf became transformed into a shoot bud. It appears, therefore, that the induction in the primordium of dorsiventral symmetry and of the biochemical conditions characteristic of leaf growth is initially due to factors extrinsic to the primordium itself and is a function of the active shoot apex, but the mechanism by which this is brought about is not yet understood.

The results of these experiments clearly provide some measure of support for the partial-shoot theory of the leaf developed by Arber^{12,13} as a result of comparative studies of angiosperms.

I am indebted to Prof. O. W. Wardlaw for his guidance and encouragement throughout the investigation. This work was carried out during the tenure of a Berry Scholarship awarded by the University of St. Andrews.

Measurement of Length and Angle in Quantum Mechanics

I WISH to point out that in the accepted theory the association of operators and observations is very intricate precisely in the simplest cases. You give me a splinter of a diamond crystal. Its state function is to be an antisymmetric function of the co-ordinates x_i of the n carbon nuclei the specimen contains. Can this function give information on the *shape* of the splinter? The label k is not connected with any location, with any point of the crystal lattice! Let the splinter be needle-shaped. I can measure its length. What operator is associated with this measurement? We must remember that only operators *symmetric* with respect to all the x_i are meaningful.

The only answer I can find to the last question is this. Let $r_{kl} > 0$ be the distance between the k th and the l th carbon nucleus ($k \neq l$). Let F be a symmetric function of the $n(n-1)/2$ variables r_{kl} , the value of F being equal to the biggest of its arguments. (This does not contradict its symmetry; for example, for $n=3$ we should have F a function of the three variables r_{12}, r_{13}, r_{23} , constant on the half-surfaces of certain cubes, its value being the edge of the cube.)

This function $F(r_{kl})$ might be associated with the measurement of the length of the needle. In order to account for the whole observed shape of a solid, the construction could be extended in an obvious way, by using as the arguments of F not the mutual distances, but the Cartesian co-ordinates of the nuclei with respect to the centre of gravity. But is this answer satisfactory?

In the case of a crystal, the elements of shape that interest us most are the angles between the various plane domains of its surface. The measurement of the angle between two crystal planes is certainly the one most frequently performed on a crystal concerning its external shape. Even an X-ray investigation of a single crystal is usually preceded by carefully orientating it with respect to a given frame; this amounts to angle measurements of a similar kind. For all these purposes no measurement of length in the crystal is required, nor is any usually made. It is hard to see how the accepted theory would associate a Hermitic operator with this very common kind of laboratory performance.

Diffraction Gratings in Immersion

At the London Optical Conference in 1950, it was suggested¹ that the resolving power R of diffraction gratings might be increased by immersing the grating in a medium of high refracting index μ_i . Thus:

$$R = \frac{2W \sin \alpha}{\lambda} \cdot \mu_i, \quad (1)$$

where W is the ruled width of the grating and where α applies for the case of autocollimation of incidence and diffraction. This idea, which is a strict parallel

Fig. 1

to that of the immersion microscope, was further developed² in accordance with Figs. 1a and b.

If we bring a piece of coverglass into optical contact with a plane grating with an immersion film (Fig. 1a), two kinds of spectra can be observed: one produced by the uncovered grating, as indicated by the dotted line, and the other produced by the 'immersion' grating. These two spectra will coincide in all orders in accordance with Snell's law of refraction. They will, however, exhibit great differences in intensity, as the immersion spectrum is produced at a steeper angle of incidence α than the angle of incidence γ occurring at the uncovered surface:

$$\sin \gamma = \mu_i \sin \alpha. \quad (2)$$

Thus a grating characterized by a 'blaze' in an order m will have this blaze shifted into the range of $\mu_i m$ when it is used as an immersion grating. Striking illustrations of this effect were obtained from photographs of the grating surface. Thus a piece of coverglass, which was fastened to the grating by an immersion oil, appeared in bright or dark contrast to the uncovered part of the grating, when illuminated in different orders of monochromatic light.

Some experiments were also made with ruling gratings on transparent films of antimony trisulphide and zinc sulphide, evaporated in vacuum on the 'back' surface of plane glass plates, afterwards aluminizing the ruled surfaces for reflexion. These films of very high refractive indices ($\mu > 2$) were, however, very brittle, so that the grating surfaces soon began to crack. (The proper name 'refraction grating' given earlier³ refers only to this special application of the immersion principle with diffraction gratings.)

A second method of testing the immersion principle will now be reported. In the ordinary dense-ruled gratings, the blaze generally appears in the first or second orders of spectrum, corresponding to angles of incidence less than 20° . In the coarse-ruled gratings, however, the blaze sometimes appears at high angles of incidence $\approx 60^\circ$. When applying the method of immersion to a grating of this type, it is advantageous

Fig. 2

to let the beam pass through a prism or a side facet in the glass plate as indicated in Fig. 1b. For simplicity we may assume that the refraction indices of the prism and the immersion oil are equal, otherwise the conditions of the system, Fig. 1b, must be treated in more detail. Fig. 2 illustrates the considerable gain in the dispersion and resolving power of a plane grating, $W = 93$ mm., when it was immersed in α -bromonaphthalene and covered by a $80^\circ/60^\circ$ dense flint glass prism. The perfect resolution of the narrow doublet $0.566/0.505$ cm.⁻¹ in the hyperfine structure of the mercury line $\lambda 4358$ indicates that the spectroscopic resolution is well above 400,000.

Further details of this investigation will appear in *Arkiv för Fysik*.

Use of High Contrast in the Photography of Interference Fringes

In a recent communication, Hough and Goldsmith¹ have described a method of increasing the sharpness of interference fringes by high-contrast photography with controlled exposure. Although the technique does not appear to be widely known and I have no knowledge of any published material on the subject, the method is not new and has been in use here for a number of years.

For the case of infinite contrast, which is the only case in which the widths of dark and light fringes may be adequately defined, a curve relating black/white ratio to exposure for a single photographic process may be obtained by considering the intersection of the curves $I = \sin^2 x + A$ (light intensity) and $I = B$ (threshold at which the dark-light transition on the plate occurs), where I is light intensity, x is distance perpendicular to fringe direction and A and B are constants depending on fringe visibility and exposure. The lengths of the intercepts of $I = B$ below and above $I = \sin^2 x + A$ give the widths of dark and light fringes respectively. Fig. 1 shows a curve for 100 per cent fringe visibility ($A = 0$).

Experimentally it has been found that, over the exposure range 0-7, results are in good agreement with theory; but above this value measurement of fringe-widths becomes difficult, and black/white ratios greater than 5.5 are difficult to obtain. In order to obtain the best results in the over-exposure region,

Fig. 1

Fig. 2

two points require attention. First, developer fog must not be allowed to appear; the use of an efficient stop-bath after development is useful for this. The second condition is that the fringe-spacing must not be too small. Using Ilford R.40 plates, a separation between fringes of 2 mm. on the plate appears to be necessary for the best results. With a fringe-spacing of 0.5 mm. a black/white ratio of 3.5-4 seems to be the best obtainable.

Where a double photographic process (negative and print) is used, the following technique gives good results. The negative is given an exposure of about 4 and developed to only a moderately high contrast. By printing on a contrasty material with minimum exposure, a final result with white/black ratio about 6 may be obtained.

While this type of process can give much more accurate results than are normally expected from double-beam interferometry, some care must be exercised to prevent errors due to uneven illumination. A typical interferogram is reproduced herewith (Fig. 2).

Ferroelectric Structure of Potassium Dihydrogen Phosphate

SLATER'S theory¹ of the origin of the ferroelectricity shown by potassium dihydrogen phosphate below 120° K. is based on the assumption that the proton of the O—H—O bond is situated in a double potential well. Above the Curie point, the proton is not permanently located in either well and moves between the two, giving the structure non-polar tetragonal symmetry. Below the Curie point the proton positions are ordered in accordance with the polar orthorhombic symmetry.

Fig. 1. Projection on (001) of the density of neutron scattering due to hydrogen atoms in potassium dihydrogen phosphate at -180°C . Contours are drawn at intervals of 50 units. Broken lines are negative contours and the zero contour is shown dotted; no positive contours appear. The small circles mark the positions of the potassium, phosphorus and oxygen atoms.

In a recent paper¹, we have discussed the structure at room temperature of potassium dihydrogen phosphate as determined by neutron diffraction. We have shown that the proton distribution is elongated along the O—H—O bond; but it is not possible to decide whether this is due to the existence of a double potential well or to a normal anisotropy of thermal agitation. If the former is in fact true, then we have found that the two minima are displaced by about $\pm 0.18\text{ \AA}$ from the centre of the O—H—O bond.

We have now obtained some results on the structure in the ferroelectric state, the crystal being maintained as a single domain by means of an electric field. We find that here the hydrogen atom is situated asymmetrically between the oxygens, in an ordered arrangement to satisfy the *Fdd* symmetry as supposed by Slater. A projection of scattering density on the (001) plane is shown in Fig. 1; this can be contrasted with Fig. 10 of our earlier paper¹, which shows the same portion of the structure at room temperature. The projection shows the Fourier synthesis of hydrogen atoms only, as obtained from the quantities $F_{\text{obs.}} - F_{\text{KPO}}$, where $F_{\text{obs.}}$, F_{KPO} are respectively the observed structure factors and those due to potassium, phosphorus and oxygen calculated from the positions of these atoms given by a direct synthesis of $F_{\text{obs.}}$. For convenience the positions of these atoms are marked by circles in Fig. 1. The hydrogen atom is displaced by $0.21\text{ \AA}$ from the centre of the O—H—O bond, the symmetry being such that throughout a single domain all the hydrogens are displaced towards, say, 'upper' oxygen atoms, O_1 , of PO_4 groups in accordance with Slater's model. On reversing the electric polarization, they are all displaced towards 'lower' oxygens, O_2 .

We find no significant movement of the oxygen atoms from their room-temperature positions in the *xy*-plane. If there is no substantial departure of the

O—H—O bond from the horizontal, as seems likely from Frazer and Pepinsky's X-ray measurements², it follows that the two portions of the O...H...O bond will be 1.04 and $1.45\text{ \AA}$, respectively.

Full details of these investigations will be presented in due course.

Permeation of a Membrane in the Presence of Water-Flow Induced by Hydrostatic Pressure

THE present status of the quantitative theory of membrane transport processes in the absence of water-flow has been almost fully verified by the available experimental evidence. It is also a fact that in many artificial and biological membrane systems the effect of the water-flow, though undoubtedly present, can be neglected because of its small size. In other membrane systems this may not be so. It should be emphasized that the mere knowledge of rate of flow of a volume of water through a certain area does not give the velocity of the water-flow in the membrane.

In the flux equation, the influence of net solvent-flow can be expressed as an additive flux term equal to the velocity of water-flow times the concentration of the component studied at the membrane point considered¹. The integration of the general equation describing the simultaneous operation of diffusion forces, electrical forces and the effect of fixed membrane charges as well as net solvent flow forces remains to be done. Manegold and Sol² solved the equation for an uncharged particle in a special case by employing the relation given by Hertz³. A solution for the general case, omitting only the effect of fixed membrane charges, has been suggested by Teorell⁴. In the interesting case where the ratio between influx and outflux is considered, solutions were given by Ussing⁵ and Teorell⁶.

Little attention has been given to an experimental approach to the phenomena¹. In order to try to verify the theoretical statements, the following experiments have been carried out. In a dual diffusion

chamber system, one compartment was closed and connected to a constant-pressure device. A fairly permeable cellulose filter-membrane (effective area for heavy water diffusion about 30 per cent) separated the two compartments. A constant known flow of water could be obtained and the permeation of a test substance against the flow could be measured. The accompanying graph shows the result for deuterium-labelled water as the test substance. The total flux of water against the mass flow is plotted against the net flux, which, in this case, is equal to the velocity of the streaming water times the area available for flow. The curve is plotted from the relation:

$$\Phi_{\text{out}} = \frac{\Delta w}{\exp(\Delta w \cdot \delta / A R T w') - 1}$$

where Φ_{out} is the total flux of water out, Δw is the net flux of water, A is the area available for flow, R the gas constant, T the absolute temperature and w' the mobility of the water molecule in the membrane, in this case taken to be equal to D_w/RT , where D_w is the free diffusion coefficient of water in water. δ is equal to the membrane thickness. The experimental observations seem to follow the theoretical curve quite satisfactorily (see figure).

A full report of these experiments and others in progress will be published later.

Sidereal Correlation of High-Energy Cosmic Rays

EXTENSIVE air showers have been recorded at Auckland (altitude 40 m.) during the period February 1951–February 1952 inclusive, with three counter trays each of sensitive area 2,560 cm.² placed at the corners of an equilateral triangle with 4 m. sides. About 3×10^6 events have been recorded. Averaged over the year, the results show a solar diurnal variation of 1.46 ± 0.16 per cent (first Fourier amplitude with statistical probable error), with the maximum at 2.9 ± 0.4 hr. local solar time. This correlates well with temperature.

When the number of showers occurring in half-hourly intervals of sidereal time is averaged over the year, the figures show a sidereal variation with first Fourier amplitude 1.06 ± 0.16 per cent with the maximum at 19.3 ± 0.6 hr. local sidereal time. This result is similar to the Fourier amplitude of 0.89 ± 0.13 per cent with a maximum at 22 ± 1.3 hr. local sidereal time obtained by Daudin and Daudin¹ in 1951 at the Pic du Midi for extensive air showers recorded with a different arrangement of counters.

A seasonal variation in the solar diurnal effect would give an apparent sidereal effect when the results are expressed in sidereal time and averaged over the year. In this case, provided the solar seasonal effect is the same in the southern as in the northern hemisphere, we would expect the apparent sidereal variation obtained in the two hemispheres

to differ in phase by 180° . In fact, the variations observed at Auckland (lat. 37° S.) and the Pic du Midi (lat. 43° N.) are in phase, and the maxima coincide in local sidereal time almost within the probable error. This gives grounds for believing that the variation observed is a genuine sidereal effect and is not a residuum due to seasonal changes in the solar diurnal variation.

Although the times of the maxima at Auckland and the Pic du Midi do not agree exactly, at both places the local maximum coincides closely with the time at which the Milky Way is overhead. This suggests that cosmic rays come preferentially from regions of high star density.

At Auckland the maximum is not far from the time (18 hr. local sidereal time) at which the centre of the Galaxy crosses the meridian. The declination of the galactic centre is -26° . This means that it passes daily within 11° of the vertical at Auckland, but only within 69° of the vertical at the Pic du Midi. Any effect due to cosmic rays coming from the central region of the Galaxy should therefore be much stronger in Auckland than in Europe. This accords with the fact that our sidereal amplitude is nearly three times as large as that obtained at the Pic du Midi. The results therefore indicate that more high-energy cosmic rays are observed when the centre of the Galaxy is overhead.

We cannot reconcile these results with those of Ballario, Brunelli, de Marco and Martelli², who observed dense showers on the Testa Grigia for a period of three months and obtained a maximum at about 10 hr. Central European Time, which we find corresponds to 5 hr. local sidereal time.

One of us (J. R. S.) is indebted for a fellowship to the University of New Zealand Research Committee, which also gave a grant covering the major cost of the apparatus.

Motion of the Storm-D Regions

W. R. PIGEON¹ has reported coherent variations with longitude which he interprets as motion of the "storm-D regions" once around the earth in 48 hr. This result is based on the data of about three years from each of six vertical-incidence ionospheric stations. Work at the National Bureau of Standards, however, based on ionospheric data tabulations from seventeen stations for the four years, 1949–52, does not support the hypothesis of coherent motion of such regions.

Reference will be made here to (per cent) 'probability of blackout' rather than to storm-D regions. Diurnal variation of blackout probability is determined by counting the number of instances (at each hour for the four-year period) of excessive absorption. In these cases the letter B is the standard symbol used to replace a numerical value for all the ionospheric parameters normally scaled: f_0F_2 , $h'F_2$, f_0F_1 , $h'F_1$, f_0E , $h'E$.

Blackout may often be a misnomer, since the no-echo conditions can also arise if the equipment lacks

Fig. 1. Average probability (per cent) of blackout (A_0)

sensitivity and if absorption is only moderate. Moreover, Watts and Brown³ have shown recently that at Washington, for example, 'no-echo' in the 1-25 Mc./s. range may be accompanied by F -layer reflections with f_oF_2 less than 1 Mc./s., that is, at times of extremely low absorption. In general, it is impossible to differentiate among the three conditions: (1) blackout, (2) low sensitivity with moderate absorption, (3) f_oF_2 less than 1 Mc./s., by use of the tabulation sheets alone. The no-echo conditions, due to any of the three causes, is the subject of this communication, but the term 'blackout' will be used throughout. It is assumed that data from different stations are directly comparable.

The diurnal curves may be approximated (in general, quite closely) by the constant term and first harmonic of a Fourier series: per cent probability of blackout = $A_0 + C_1 \cos 15(t - \phi_1)$, where A_0 is average per cent probability, C_1 is amplitude (per cent) of the first harmonic of the diurnal variation, ϕ_1 is time (in hours) at which the first harmonic reaches a maximum (ϕ_1 , of course, may

Fig. 2. Amplitude of diurnal variation of probability (per cent) of blackout (C_1)

be expressed in local time for each station or in universal time).

Contour plots of A_0 (Fig. 1), C_1 (Fig. 2) and ϕ_1 (Fig. 3) are shown. The minimum shown on the plot for A_0 (or C_1) over North America, north of the auroral zone, is perhaps surprising; but its existence has long been suggested by the relative ease of maintaining radio communications inside the auroral zone. A recent study⁴ of continuous-wave field-strength data gives additional evidence. The presence of this minimum suggests that rotation about the geographical pole is not likely, although such motion, possibly about the dip pole, is not ruled out.

The ϕ_1 plot (Fig. 3) does not suggest motion of the sort proposed by Piggott, nor does it suggest motion of any sort except that which is apparent in the case of any phenomenon depending primarily on local time. More important, however, is the fact that no simple longitudinal motion can account for the large, relatively complex latitude variations of

Fig. 3. Time (L.M.T.) of maximum probability of blackout (ϕ_1)

A_0 and C_1 . Motion, in a study of this kind, should be shown by comparison of plots of equal probability contours for successive hours of universal time: that is, the chart for 0000 G.M.T. should differ from that for 0100 G.M.T., etc., in such a way that speed and direction of the motion can be determined. Plots of this kind have been attempted, but appear to have little meaning and do not exhibit the motion suggested by Piggott.

It is concluded that a 48-hr. rotation of the storm- D regions is not indicated.

There is a large seasonal variation in blackout probability as well as variations with magnetic disturbance. These, as well as a more detailed account of the work referred to above, are being incorporated in a paper now in preparation.

Reduction in the Loss Factor of Certain Ceramics by Heat Treatment

It has been suggested by Breckenridge¹ that one of the main reasons for the absorption of energy in a.c. fields by alkali halide crystals is the presence in these crystals of pairs of associated lattice defects on adjacent sites. Breckenridge carried out measurements on various halide crystals, and he found in some cases that it was necessary to heat-treat a crystal at a temperature within 25° C. of its melting point, following this treatment by fairly rapid cooling, in order to produce a sufficient number of lattice defect pairs for the energy absorption to be measurable.

This suggested to me that it might be worth while to attempt to reduce the dielectric losses in steatite, forsterite and other ceramics by a prolonged heat treatment at a temperature well below the firing temperature of the ceramics. The heat treatment was chosen quite arbitrarily as 60 hr. at 1,000° C. The values of dielectric constant (K) and the tangent of the loss angle ($\tan \delta$) were determined at 10 cm. before and after heat treatment. Some of the results obtained are given in the accompanying table.

Ceramic	Before heat treatment		After heat treatment	
	K	$\tan \delta$	K	$\tan \delta$
A	5.8	15×10^{-4}	5.8	4×10^{-4}
B	6.8	6×10^{-4}	6.8	4×10^{-4}
C	6.1	4×10^{-4}	6.2	9×10^{-4}
D	6.6	7×10^{-4}	6.6	1×10^{-4}
E	6.2	5×10^{-4}	6.2	8×10^{-4}
F	6.8	2×10^{-4}	6.8	9×10^{-4}
G	6.0	1×10^{-4}	6.0	4×10^{-4}
H	6.3	1×10^{-4}	6.2	4×10^{-4}
I	6.3	7×10^{-4}	6.1	2×10^{-4}
J	5.4	2×10^{-4}	5.0	2×10^{-4}
K	5.4	1×10^{-4}	5.6	3×10^{-4}

Of these ceramics, A is a British commercial low-loss steatite ceramic, the remainder are materials made in the British Thomson-Houston Research Laboratory. Ceramics B-E are forsterite, F is a wollastonite material and the remainder are steatites. The table shows that in the majority of cases the heat treatment has caused a reduction in the value of $\tan \delta$, although in one case an increase was observed. This is to be expected in view of the arbitrary way in which the heat treatment was chosen. It should be noted that many of the values of $\tan \delta$ quoted in the table are much lower than those previously quoted for ceramics of similar chemical composition. It seems likely that this type of heat-treatment process will make possible the commercial production of ceramics having much better loss properties than those hitherto available².

It is realized that, although the heat-treatment experiments were suggested by Breckenridge's work, it does not follow that the effect observed is caused by a reduction in the number of lattice defect pairs; it may well be that it is caused mainly by devitrification of the glassy phase in the ceramics. This point can only be settled by further experiments. To study the effect completely, it would also be necessary to make measurements over a considerable frequency-range and perhaps also over a range of temperature.

I am indebted to Miss J. E. J. Dods, who prepared the ceramics, and to Mr. J. H. B. Baker, both of this laboratory, who made the dielectric measurements; and also to Mr. L. J. Davies, director of

research, for permission to publish this communication.

Adsorption of Prostatic Phosphatase on Ion-exchange Resin

In recent years the proteins cytochrome c¹, ribonuclease², lysozyme³, and haemoglobin⁴ have been successfully chromatographed on the carboxylic acid ion-exchange resin 'IRO 50'. Experiments with proteins on the sulphonated polystyrene ion-exchange resin 'Dowex 50' have also been reported⁵.

In the only case where an enzyme has been separated from a crude extract by the use of a column of 'IRO 50', the enzyme studied seems to be the only one to be adsorbed on the resin, while most of the other proteins pass right through the column. The fact that proteins often are not adsorbed on ion-exchange resins has also been utilized for desalting of proteins⁶. When, however, a protein can be adsorbed on—and later desorbed from—an ion-exchange resin the procedure might offer a fairly selective, yet mild and convenient method of purification.

This communication describes a partial purification of seminal prostatic phosphatase by adsorption on 'Dowex 50' and elution with a pH gradient. The principle of gradient elution has been outlined earlier⁷. The method is carried out here in such a way that an alkaline buffer will continuously replace the more acid starting buffer and thereby slowly change the pH of the eluting agent.

The enzyme solution used was obtained from normal human semen in the following way. The semen was diluted five times with 0.9 per cent sodium chloride solution and centrifuged at 2,000 *g* for 15 min. in order to remove the spermatozoa. The remaining solution was dialysed against a 0.2 *M* sodium acetate buffer of pH 5.4 (in the following referred to as the acetate buffer).

The phosphatase activity was determined at pH 5.5 according to Beesey *et al.*⁸, using *p*-nitrophenyl phosphate as substrate.

The resin used was 'Dowex 50- $\times$ 8', 200–400 mesh, pretreated according to Moore and Stein⁹ and finally washed with the acetate buffer. This pretreatment is essential—otherwise the enzyme is adsorbed so strongly that it cannot be eluted. After an experiment the column may be regenerated by washing with 1 *N* sodium hydroxide.

Most of the experiments have been performed on a small scale, the dimensions of the column being 8.0 cm. $\times$ 0.55 cm. The temperature was kept at 4° C. Usually, 0.3 ml. enzyme solution was applied to the column, the mixing chamber (volume 1.2 ml.) was filled with the acetate buffer and the open top chamber with a Palizsch's borate buffer of pH 7.3. The fraction collector used here shifted the tubes every 18 min., and the mean volume of the fractions was about 0.5 ml., although varying considerably during each experiment.

Fig. 1 gives the results of an experiment carried out as described above. The full line represents the

Fig. 1. Small-scale experiment with prostatic phosphatase on a column of 'Dowex 50'. Full line represents phosphate activity in moles of substrate split during 30 min. at 37° C. Dashed line represents extinction at $\lambda = 280 \text{ m}\mu$.

phosphatase activity and the broken line the extinction for ultra-violet light ($\lambda = 280 \text{ m}\mu$). As can be seen, the enzyme comes out as an extremely narrow zone and all the activity is collected in one fraction. About 75 per cent of the activity of the starting material is recovered.

The nitrogen concentration per unit activity of the active fraction shows that this chromatographic procedure gives at least a five-fold purification of the enzyme.

There are some difficulties in estimating the inactive protein material from the column. Using ultra-violet extinction, there is the risk of interference from low-molecular resin material which may be displaced from the column by proteins and therefore may appear in the eluate despite all the pre-washings. The Folin reagent was tried but gave unreasonable figures. Kjeldahl analysis has been used, but in most of the fractions (with the exception of that containing the enzyme) the concentration of nitrogen is too low to permit accurate determinations. However, both the

ultra-violet extinction measurements and the Kjeldahl determinations show that some of the inactive material passes readily through the column whereas a large part remains on the resin.

Fig. 2 shows part of the results from an experiment performed on a scale fifty times greater than the previous one. The activity and ultra-violet extinction curves for the enzyme zone are shown in Fig. 2A, while Fig. 2B gives the pH values for the corresponding fractions. The interval between the shifts of the tubes was the same as before (18 min.). The volumes of fractions 35 and 45 were about 10 ml. and 6 ml. respectively.

It is to be expected from the method that a zone will appear near the maximum of the slope of the gradient. This can also be seen from a comparison of Fig. 2A and 2B, which shows that most of the enzyme is eluted between pH 5.5 and 6.5. The ultra-violet extinction measurements and Kjeldahl determinations indicate that some inactive material follows directly after the enzyme. A buffer system with a larger buffer capacity in the effective pH region would therefore be expected to give still better separations.

London and Hudson⁶ have recently reported a purification of the prostatic acid phosphatase starting from prostate glands. One of the preparative steps they used was adsorption on calcium phosphate gel, which gives a two-fold purification. It is difficult at present to compare the purity of their enzyme with that obtained here after adsorption on 'Dowex 50'. In any event, it is felt that this adsorption procedure will be a useful complement to other preparative methods.

The work is being continued, and full accounts will be published elsewhere. I wish to thank Prof. A. Tiselius for his interest in this work.

Radioautographic Studies of the Digestive Tracts of Rats Injected with Inorganic Sulphate labelled with Sulphur-35

BÉLANGER¹ recently reported the presence of sulphur-35 in the neck cells of the gastric glands of the rat following the administration of sulphuric acid labelled with sulphur-35 by subcutaneous injection. We wish to report that we made similar observations during the course of a radioautographic study of the distribution of sulphur-35 in the rat following the administration of radioactive inorganic sulphate. The techniques employed in this work and some of the results obtained have already been reported². Sodium sulphate labelled with sulphur-35 was administered to rats by intraperitoneal injection,

and after various intervals the animals were killed, tissues were removed and contact radiosautographs were prepared. Four hours after dosing there was considerable accumulation of sulphur-35 in the necks of the gastric glands, whereas radioactive material was absent from that part of the stomach lined with stratified squamous epithelium. More intense radiosautographs were obtained from the intestinal glands (crypts of Lieberkühn). The most striking localization of sulphur-35, however, was observed in the small mucous-secreting salivary glands which lie in relation to the masseter muscle and are presumably posterior members of the molar group (Figs. 1 and 2). These results were in marked contrast to those obtained from the adjacent parotid gland present in the same sections, where the intensity of the radiosautograph

(1) Section, 50 μ thick, of a mucous-secreting salivary gland from a 190-gm. rat injected intraperitoneally 4 hr. previously with sodium sulphate labelled with sulphur-35 (approx. 3 μ c. of sulphur-35 per gm. body-weight). Hematoxylin and eosin. (2) Corresponding contact radiosautograph. Both $\times 80$. (3) Section, 50 μ thick, of the parotid gland of the same rat. Hematoxylin and eosin. (4) Corresponding contact radiosautograph. Both $\times 80$.

was in general very low, and was less for the actual glandular tissue than for the capsule (Figs. 3 and 4). Other mucous-secreting salivary glands have not yet been investigated.

The distribution of sulphur-35 observed in these experiments suggests strongly that it was secreted as sulphomucopolysaccharide. If this proves to be so, inorganic sulphate labelled with sulphur-35 should serve as a useful tool for investigating the distribution and activity of mucus-secreting cells.

Detection of Fingerprints by the Ninhydrin Reaction

IN connexion with some recent legal proceedings, a new method for detecting fingerprints has been discovered by one of us (S. O.). The method involves the well-known ninhydrin test for amino-acids, often used in chromatography. In this method, fingerprints on paper have always been considered a great nuisance, and one is often recommended to use forceps "to avoid fingerprints"¹. In our opinion, the new method will be most suitable for detecting fingerprints on paper and similar materials. Some of the results have a wider interest, and a brief report on the new application of ninhydrin is therefore presented.

When handling a paper, a person may leave his fingerprints on it, depending on many factors such as physiological conditions, time of contact between the fingers and the paper and other unpredictable circumstances. A spontaneous fingerprint contains 98.5–99.5 per cent water, the rest being organic and inorganic compounds. Normally, the water will evaporate, leaving the rest as a fingerprint pattern containing fats, salts, amino-acids, etc. The last group of substances gives the well-known reaction with ninhydrin. Since perspiration contains water-soluble amino-acids (at least ten amino-acids have been found²) a moist finger or a moist paper is necessary if fingerprints on paper are to be made visible by the ninhydrin reaction.

Fingerprints are developed by spraying the paper with a 0.2 per cent solution of ninhydrin in acetone, followed by heating the paper in an oven at 80° C. for a few minutes. This initiates the process, and the strongest marks become visible. The pink colour becomes more intense with time, and new marks appear as the developing process matures. Details seem to have a maximum distinctness a day or two after the ninhydrin treatment.

After treating a paper with ninhydrin, it must not be touched by hand; otherwise new fingerprints will develop even if the paper is dry. This is a fact well known to everybody working on the paper chromatography of amino-acids and similar substances. In the presence of a solvent, for example water, contact with fingers gives soft pink spots with no clear lines. Even on dry paper the papillary lines become clearly visible.

Fig. 1. (a) A twelve-year old fingerprint in a French grammar; on almost every page fingerprints could be developed by ninhydrin. (b) A fresh print as reproduced for comparison.

We have been able to develop fingerprints on many kinds of paper, some of which had not been touched for a long time. Fig. 1 shows part of a page of a French grammar which had not been used for twelve years. The owner's fingerprint can be compared with a fresh print developed on sized paper.

We are investigating the ninhydrin reacting compounds in fingerprints and perspiration. Fingerprints have also been made visible with *Amidoschwarz* (Bayer) or other reagents used for the localization of protein spots in paper electrophoresis. This indicates the presence of proteins, probably keratin.

All the details and applications of the method have not been worked out yet; but a full account of problems related to it will be published elsewhere. Part of this work has been carried out at the Institute of Biochemistry, Uppsala, and we are indebted to Prof. A. Tiselius for valuable discussions.

Occurrence and Distribution of Sarcosine in the Rock Lobster

THE unidentified amino-acid found by us in the rock lobster (*Jasus lalandii*)¹ has been shown to be sarcosine. We are indebted to Mr. R. G. Westall for suggesting that our unknown might be sarcosine and for sending us an authentic sample for comparison.

We had previously considered this possibility, but had rejected it because the R_F values of the unidentified amino-acid in phenol and butanol-acetic acid were appreciably different from the values reported for sarcosine in the literature^{2,3} and because it did not give the colour test with *p*-nitrobenzoylchloride described for sarcosine by Plattner and Nager². However, the test also gave negative results with sarcosine in our hands, and a direct comparison of the R_F values of the unknown and sarcosine in different solvents showed them to be identical, as may be seen from the following figures:

Solvent	R_F		
	Unknown	Sarcosine Found	Literature
Phenol - water (70:30)	0.88	0.88	0.80 (ref. 2) 0.78 (ref. 3)
Butanol - acetic acid - water (40:10:50)	0.19	0.19	0.24 (ref. 3)
Lutidine - water (3:1)	0.21	0.21	—

The difference between our R_F values and those of other workers may be due to the fact that our chromatograms were of necessity run at 30°.

Final proof of the identity of the unknown was obtained by isolating sarcosine from rock lobster hepatopancreas extract by fractionation on a sulphonated polystyrene resin (nominal divinyl benzene con-

tent 4% per cent)⁴. The fraction containing sarcosine plus aspartic and glutamic acids, asparagine, proline, serine and threonine was chromatographed on a cellulose column using phenol-water (70:30) as solvent, and a fraction was obtained which contained only sarcosine and proline. This was crystallized from methanol-acetone⁵ to give chromatographically pure sarcosine, melting point 210.5-211.5° (decomp.), undepressed on admixture with the authentic sample. An examination of the infra-red spectra confirmed the identity of the two samples.

Appreciable amounts of sarcosine have been found in triphloroacetic acid extracts of the hepatopancreas and blood of the rock lobster; but only traces were found in the muscle extracts. Hydrolysates of the hepatopancreas, blood and muscle proteins did not contain detectable amounts of sarcosine. The distribution of other amino-acids in the muscle and hepatopancreas extracts will be reported elsewhere.

We are aware of only two previous reports of the occurrence of sarcosine in the animal kingdom. It was isolated from the starfish *Astropecten* by Kossel and Edlbacher⁶ in 1915, and it has recently been found in elasmobranch fishes by Shewan⁷. We have also found it in the freshwater crab *Potamon (Potamonectes) perlatus/sydneyi*, and we plan to look for it in other invertebrates.

Milk Ejection resulting from Mechanical Stimulation of Mammary Myoepithelium in the Rabbit

THERE is good experimental evidence in the rabbit^{1,2} that the normal removal of milk from the maternal mammary glands during suckling depends on a reflex release of oxytocin from the posterior pituitary gland. Histological studies^{3,4} indicate that the oxytocin induces contraction of the mammary myoepithelium, which results in the expulsion of the milk stored in the alveoli and ducts. The present experiments, which were carried out with twelve lactating rabbits, disclosed a subsidiary mechanism of milk ejection which may help to explain the small variable amount of milk yielded to the young when posterior pituitary activity is prevented by denervation of this gland, by anaesthesia⁵, and by emotional excitement⁶.

The animals were suckled by their litters prior to the experiments. They were anaesthetized with ethanol-urethane⁷, the abdomen shaved and a single teat duct of one mammary gland cannulated. Up to 5 ml. of normal saline at 37°C. was introduced through the cannula until the gland segment served by the cannulated duct was sufficiently distended to

stand out from neighbouring glandular tissue. The cannula was connected to a piston-recorder writing on a kymograph.

A sharp tap delivered with the flat surface of a scalpel handle on the cannulated segment of the mammary gland resulted after a latent period of about 1 sec. in a rise of 1–10 cm. of the fluid in the cannula, representing an ejection volume of 0.06–0.6 ml. The total duration of the response was less than 1 min. (Fig. 1). A succession of taps at intervals of approximately 10 sec. resulted in a partial tetanus and rapid onset of fatigue (Fig. 1a). The responses resembled those produced by small doses of oxytocin. When a tap stimulus was given at the onset of a near-threshold dose of oxytocin, a smooth summated response was obtained (Fig. 1a). But tap stimuli applied during a response to a near-maximal dose of oxytocin were ineffective (Fig. 1b). This result indicates that the responses to hormonal and mechanical stimuli utilize the same effector tissue (myoepithelium).

The response to tap stimuli was not affected by procaine infiltration of the overlying skin, and typical ejection responses could be elicited after removal of a portion of the skin by direct application of the tap stimuli to the exposed mammary tissue. Substitution of 4 per cent procaine for saline in the cannula also did not prevent responses to the tap stimuli. Further, section of the inguinal (external spermatic) nerve supplying sympathetic adrenergic fibres to the inguinal mammary glands did not affect the response in those glands, and electrical stimulation of the peripheral end of the nerve, or injection of adrenaline or nor-adrenaline, did not produce an ejection response. These observations favour the view that the tap stimuli activate the contractile elements directly, without nervous intervention.

Other experiments which will be reported in detail elsewhere showed that procedures which stimulate sympathetico-adrenal activity in the rabbit inhibited

the milk-ejection response to intravenous injection of oxytocin, but not the response to tap stimuli. These results provide suggestive evidence that the inhibitory effect of sympathetico-adrenal activity⁴ is mediated indirectly by mammary vasoconstriction rather than by a direct inhibition of myoepithelial contraction.

A Billiviolin Metal Complex in Ox Bile

An ethyl acetate extract of fresh ox bile acidified to 5 per cent with concentrated hydrochloric acid yielded a dark green waxy solid on taking to dryness *in vacuo*. Chromatography of this substance from a 2 : 10 methanol – ether solution on a column consisting of a mixture of 12 gm. of acid-washed talc and 3 gm. 'Hyflo' filter-aid gave a single grey-green band which could be partly eluted with methanol. The absorption spectrum of the eluted substance (a green solid) in methanol and in methanolic hydrochloric acid is shown in the accompanying figure. Acidification changed the colour of the solution from green to violet and shifted the absorption maximum from 646 to 568 mμ. A chloroform solution of the compound showed a strong red fluorescence in ultra-violet light. The pigment could not be extracted from

Absorption spectrum of the green pigment obtained by chromatography of an ethyl acetate extract of ox bile, in methanol (---), in 5 per cent hydrochloric acid in methanol (—)

chloroform solution with 1 per cent hydrochloric acid, demonstrating that it was biliviolin and not a bilipurpurin complex.

The zinc complex of biliviolin prepared by oxidation of a pure specimen of bilirubin showed an absorption maximum in methanol at 644 mμ shifting to 569 mμ on addition of hydrochloric acid, the colour of the solution changing simultaneously from green to blue-violet.

Biliviolinoid pigments have been observed in dog bile¹ and in gall-stones², but have been considered to be almost certainly secondary oxidation products of bilirubin. It is unlikely that the biliviolinoid pigment found in ox bile arises in this way, as its typical absorption spectrum has been found in association with an undistorted bilirubin curve. This suggests that the pigment occurs *per se* in the bile, as oxidation has been found always to be accompanied by distortion of the bilirubin spectrum. Such a compound would probably occur normally in bile in the form of a trace metal complex, for a number of such elements are known to be excreted mainly in the bile, and the pH of ox bile (7-8) is such as to allow the formation of metal complexes.

Stearolic Acid, an Essential Fatty Acid?

ACCORDING to Bernhard¹, stearolic acid (Δ^8 -octadecynoic acid-1; $\text{CH}_3-(\text{CH}_2)_7-\text{C}\equiv\text{C}-(\text{CH}_2)_7-\text{COOH}$) has vitamin F activity, since this acid, when mixed throughout the diet in the form of its ethyl ester, prolongs the life of vitamin F-deficient rats.

This result is in contradiction with our investigations², in particular with the '6,9(term.)-hypothesis'. According to this hypothesis, the presence of two double bonds at the 6,9(term.)-positions of fatty acids (that is, double bonds at the 6:7- and 9:10-positions when numbered from the terminal CH_3 -group) is essential for vitamin F activity. The known essential fatty acids, namely, linoleic, linolenic and arachidonic acid, are all characterized by this 6,9(term.)-configuration. On assaying a large number of fatty acids, it appeared that acids which do not have this characteristic are inactive, and further, three new essential fatty acids were found, namely, $\Delta^{10,12}$ -nonadecadienoic, $\Delta^{11,14}$ -eicosadienoic, and $\Delta^{6,9,12}$ -octadecatrienoic acid, all characterized by the occurrence of double bonds at the 6,9(term.)-positions.

The activity of stearolic acid has now been investigated by means of our new method³ for the standardization of vitamin F. Using this method, male weanling rats received a limited amount of drinking water—14 ml./day/animal. The food was given in the form of a fat-free sucrose diet. The preparatory period lasted for seven weeks, and was followed by a four-week test period.

Five times per week 0.2 ml. of the various preparations was pipetted to groups of twelve and twenty-four animals respectively, except the control group (eleven animals) which received nothing. The groups forming the reference standard received various doses

of sunflower-seed oil, which, if necessary, were made up to 0.2 ml. with fully hardened coconut fat, which contains no linoleic acid. The stearolic acid was administered as the ethyl ester. The stearolic acid ester was prepared from oleic acid by bromination to dibromo-oleic acid, followed by dehydrobromination with aqueous potassium hydroxide. The stearolic acid thus obtained melted at 47.2-47.3° C., was free from bromine and optically pure. It was esterified in ethanol/sulphuric acid.

Probably as a result of the longer preparatory period (normally five weeks) some of the animals died. Moreover, a number of the animals developed lesions at the tip of the tail. In its final stage the lesion amounted to a complete necrosis of the tail tip; this stage was assigned the figure 3, while 2 and 1 represented less serious stages, and 0 the normal tail.

The data on the mortality, the tail lesions, and the change in the body-weight during the four-week test period are collected in Table 1. Owing to the mortality, the data regarding the change in the body-weight relate to the surviving animals.

Table 1. MORTALITY, EXTENT OF TAIL LESIONS, AND CHANGE IN THE BODY-WEIGHT OF VITAMIN F-DEFICIENT ANIMALS RECEIVING DIFFERENT DOSES OF SUNFLOWER-SEED OIL AND STEAROLIC ACID DURING A PERIOD OF FOUR WEEKS

Preparation	Dosage (day/animal)	Mortality	Mean stage tail lesions	Change in body-weight (gm.)
Control	nil	2/11	0.44	-5
Sunflower-seed oil	10 mgm.	0/24	0.00	+18
"	50 "	0/24	0.00	+70
"	182 "	0/12	0.00	+86
Stearolic acid (ethyl ester)	172 "	9/12	0.92	-38

In the sunflower-seed oil groups, no deaths or tail lesions occurred, while a distinct growth reaction was observed. Of the controls, three out of eleven animals died, the mean tail lesion was 0.44, and the body-weight of the group decreased slightly (-5 gm.). Of the twelve animals which received the ethyl stearolate, nine died (significant with regard to the control group), while the tail lesions (stage 0.92) were more serious than in the control group. The stearolate did not give any improvement in the body-weight, but quite the reverse, for a significant decrease in weight was found.

A similar growth retardation in vitamin F-deficient animals has also been observed by Holman⁴ with conjugated linoleic acid, as well as in our own investigations² with a number of other fatty acids, both saturated and unsaturated.

Summarizing, the present investigation has made it clear that stearolic acid is not able to improve the survival time, tail lesions or growth of vitamin F-deficient animals; on the contrary, it affects them adversely.

I wish to thank the management of Unilever N.V. for permission to publish this work; and Mr. Sparreboom for the preparation and Mr. Duin for the esterification of the stearolic acid.

Rickets in Sheep

Elliott and Crichton¹ claimed that 'bent-leg' is of widespread distribution in Scotland. They found that cod-liver oil added daily to the diet of young rams less than a year old prevented the appearance of the rachitic condition. These observations were confirmed by Auchincloss and Fraser² and by Dunlop³. Recent experimental work by Ewer⁴ has shown that the rachitic condition occurring in Welsh lambs brought to Cambridge could be prevented by the administration of a single dose of vitamin D₃ (25 mgm. calciferol in 10 ml. arachis oil) given orally to each animal. The protective action of this large dose lasted approximately two months.

On December 20, 1951, at Dalvine Farm, Ayrshire, thirty-eight ram hogs reared on low-ground pasture from four months of age were individually numbered and weighed. The animals were allotted at random to two groups. One group comprising twenty animals (group A) received by mouth two million i.u. vitamin D. The remaining eighteen ram hogs were retained as controls (group B).

The extent of the pasture on which both groups of animals grazed together was 15 acres, which had been ploughed and re-seeded in 1950.

Blood samples drawn from the jugular vein were obtained from ten animals in each group on January 12, and again on February 9, 1952, when the live-weight of the animals in both groups was again determined. The results are shown in Fig. 1. It will be observed that the animals which received supplementary vitamin D in December made a larger gain in live-weight than did the control group.

While vitamin D has been shown to have no effect on growth-rate when ram hogs already have a sufficient store of the vitamin, half the severely rachitic animals lost weight during the experiment. The late development of the condition in the animal which made the greatest gain in live-weight in the undosed group shows clearly, however, that it is necessary for the animal to increase in live-weight before 'bent-leg' appears. Once rachitic symptoms develop, the animal is unable to move about and feed normally, at pasture or at the trough; consequently, a marked fall in live-weight rapidly follows.

The results of the blood analyses (Fig. 2) showed that whereas the serum calcium level of the dosed group was 11.3 mgm. per 100 ml., the corresponding figure for the control group was 6.78 mgm. calcium. A marked difference was also obvious even a month after dosing in the level of the blood phosphate in the two groups. The figure obtained in the undosed controls was less than 4 mgm. phosphorus per 100 ml.

Fig. 1. Live-weight gains from ram hogs during December 20–February 9. N, normal; r, rickets; R, severe rickets

Fig. 2. Blood inorganic phosphorus and serum calcium levels of experimental animals

blood in all cases. In the dosed group, however, the blood analyses showed that the level of blood inorganic phosphorus was greater than 5 mgm. per 100 ml. in every animal. The clinical condition of five treated animals a month after dosing indicated, however, that the rachitic condition was beginning to appear.

Dosing of all the animals on February 9 with two million i.u. vitamin D₃ resulted in recovery and normal health and growth in the affected untreated controls.

It is now general practice in the south of Scotland on hill farms to administer a large dose of vitamin D₃ to the young rams about mid-December and again early in February. At all experimental centres in this area (seven), two administrations during the winter have been found to be necessary.

This treatment has been found to be sufficient to prevent the appearance of the rachitic condition 'bent-leg' during the winter months.

Cytology of Meiosis in *Matonia*

Matonia pectinata R. Br. is one of the best known examples of a very ancient relict type among living ferns. As is well known¹, the fossil record goes back at least to the Cretaceous period and it extends geographically into the present Arctic Circle, yet the living species is confined to a few isolated mountains in western Malaysia.

Fig. 1. First meiotic metaphase in a spore mother cell of *Matonia pectinata* photographed with a dry lens in the original acetocarmine mount to permit all the chromosomes present to be recorded in one focal level. The two bodies surrounded by dotted lines are not chromosomes. There is one nucleolus. $\times 1,000$. $n = 26$

Matonia is at present so specialized in its ecological requirements that it has never been successfully established in cultivation although the spores have recently been germinated by Miss Alma Stokey, who has described the structure and development of the prothallia².

The opportunity to study meiosis in this species arose through the co-operation of Prof. R. E. Holttum, of the University of Malaya, who, while conducting a field-course for his own students at Fraser's Hill (Selangor-Pahang boundary) in September of this year, used the opportunity to fix sporangia in the field and to post them to me. *M. pectinata* grows sparingly on Pine Tree Hill (4,800 ft.) just below the summit. Fixings were made on September 26 in 1:3 acetic alcohol which had been taken out from England ready mixed on September 9. The material was posted from Singapore on October 3; it was received in Leeds on October 8 and the observations were completed a week later.

The stages of meiosis seen include several cells in early diakinesis and metaphase I and one damaged cell in anaphase I. All the less-perfect cells gave counts of the order of 25; but, as is demonstrated by Fig. 1, the chromosome number in the best cell obtained is unequivocally 26.

It is gratifying to note that 26 was also the number put forward by Stokey and Atkinson³ on the basis of some mitotic cells in sectioned prothallia.

It is not possible to discuss the significance of this number in detail here; but it is perhaps worth mentioning that before this result was known two species of the *Dicranopteris* section of *Gleichenia*, from Malaya and Ceylon respectively, had independently given counts of 39 and 78⁴. Since *Gleichenia* has a fossil record of the same type and age as that of *Matonia* and has, moreover, long been thought to be related to it, it is perhaps not mere coincidence that both genera should possess chromosome numbers which are multiples of the same number, namely, 13.

This subject will be discussed further in a forthcoming paper by I. Manton and W. A. Sledge on the cytology of the ferns of Ceylon. *Matonia* does not, however, occur in Ceylon, and it is therefore perhaps desirable to record the facts for it in a separate note in view of the exceptional botanical interest of the genus.

Chlamydo-spores and Survival in Soil Fungi

MANY of the fungi found in soil are centred around particles of organic debris^{1,2}, and from these food bases the fungi may spread into the soil matrix to a greater or lesser extent³. It is not known how far the fungi in the soil are dependant upon the undissolved organic matter or to what degree the nutrients in the soil solution support their growth. The work described in this communication forms part of an investigation into this question. The dilute solutions in which the fungi were grown were based on the formula given by Erikson⁴. To this inorganic artificial soil solution dextrose was added to give solutions varying from 0.005 gm./l. to 0.02 gm./l., so that the solutions might simulate a considerable range of true soil solutions. A 0.2-ml. drop of the dilute nutrient solution was placed on the surface of a clean microscope slide resting on a bent glass support in a Petri dish, the base of which contained 5 ml. sterile distilled water. A loopful, containing 20-25 conidia, of a washed spore suspension of the fungus under test was added to the culture drop, and the dishes incubated on the laboratory bench at 17.0-24.4° C. Microscopic observation of the subsequent development was made over a period of fourteen days, after staining with acid fuchsin/lactophenol. *Botrytis cinerea* Pers., *Mycoogone perniciosus* Magn., *Trichoderma viride* Pers. ex. Fr., *Trichothecium roseum* Link., *Fusarium caryosporum* Schl. var. *oubense* (R. F. Sm.) Wollenweber and Reinking, and *Stemphylium sarcinaeforme* (Cav.) Wilts. were the fungi used.

The amount of growth produced in the artificial soil solutions varied with the concentration of dextrose, but the morphological features of the colonies were identical in all the artificial soil solutions. In *Trichoderma*, *Trichothecium*, *Fusarium* and *Stemphylium*, growth was strong and macroscopically visible. In *Botrytis* and *Mycoogone* the mycelium was more tenuous, and branching of the hyphae was sparse. In all cases, growth was continuous throughout the period of observation and the cytoplasm stained deeply. Sporulation occurred in *Trichothecium*, *Fusarium* and *Stemphylium*. Control cultures of *Mycoogone*, *Trichothecium* and *Fusarium* in glass-distilled water produced germlings with short, unbranched, attenuated germ-tubes, the cytoplasm of which was disrupted and unstaining. On plating out these cultures it was found that no viable structures remained after seven days. The spores of *Botrytis*, *Trichoderma* and *Stemphylium*, however, produced small colonies characterized by the presence of terminal and intercalary swollen cells. These bodies

had a distinct double wall and the contents stained deeply in contrast to cells of the same colony with normal diameter which contained only unstaining, disrupted cytoplasm. Little further growth occurred after this stage had been reached, but on plating out the cultures normal colonies developed on the agar and, on inspection at an early stage, were seen to originate from the swollen cells of the distilled water cultures. The characters of these swollen cells agree with the criteria of chlamydo-spores as given by Langeron*.

A Seitz-filtered solution obtained from soil by displacement with water, when used as the culture liquid in place of artificial soil solution, gave restricted colonies which were morphologically identical with controls in glass-distilled water. The three fungi which had produced chlamydo-spores and remained viable in distilled water behaved in the same way here, while those which retained the usual morphology died. In a Seitz-filtered 1:5 water-extract of the same soil, development followed closely that taking place in Seitz-filtered artificial soil solution, growth continuing without the production of chlamydo-spores. The total dissolved solids in the displaced solution were greater than four times those in the water-extract, and the oxidizable organic matter greater than five times that in the water-extract. It seems probable that the characteristic development in the displaced solution was due to the presence of an inhibitory factor rather than to a shortage of nutrients.

Seitz-filtered displaced soil solution was amended with sterile dextrose solutions to give two concentrations of enriched displaced solution containing 0.01 gm./l. and 0.05 gm./l. dextrose respectively. Displaced soil solution which had been diluted an equal amount with sterile distilled water was used as control, and colonies in this solution developed exactly as in the undiluted solution. In both enriched solutions *Botrytis*, *Mycocone*, *Fusarium* and *Stemphylium* developed as in the artificial soil solutions. *Trichothecium* showed a partial inhibition with production of malformed conidiophores in the solution containing least dextrose. *Trichoderma* showed evidence of inhibition in both enriched solutions by the production of chlamydo-spores, and a reduced but continuous growth-rate. The level of dextrose in the enriched solutions was greater than that in the artificial soil solutions, yet in some cases the inhibition was still observed. The poor development in the displaced solution, then, is not due to lack of energy substances. In a displaced soil solution which had been autoclaved at 121° C. for 20 min. before Seitz-filtering, normal growth of a type morphologically identical with that found in the artificial soil solutions was obtained. The growth-rates of colonies in this solution were comparable with those of colonies in artificial soil solutions. This suggests that the abnormal development in the unautoclaved displaced soil solution was due to the presence of a naturally occurring toxin which is removed or destroyed by the heat treatment.

Concentrated washed suspensions of spores of *Botrytis*, *Trichoderma* and *Stemphylium* in distilled water were prepared with a spore density of 1.6×10^6 /litre. Drops of these suspensions were used as culture drops in an experiment to discover the effect of increased population density on the development of chlamydo-spores. Controls with 20-25 spores in each culture drop were set up in the normal way. Chlamydo-spore formation was greatly increased in all

three species and was associated with a corresponding decrease in hyphal development. Under these highly populated conditions, in fact, the colonies were largely composed of numbers of chlamydo-spores loosely held together by short lengths of moribund hyphae. In a further experiment to determine the effect of adverse conditions on the morphology of fungi of poor nutritional status, cultures of the six fungi were set up in drops of artificial soil solution in the usual way and immediately inoculated with a 23-hr. broth of an aerobic, non-spore-forming bacillus previously isolated from soil. Four of the test fungi were unaffected by the presence of this other organism and continued growth in a normal manner. Germination of *Trichoderma* and *Trichothecium* was considerably reduced by the treatment. *Trichoderma*, which had the capacity to produce chlamydo-spores, developed these bodies and remained viable with little further growth, while with *Trichothecium* the germ-tubes became markedly attenuated and ceased to grow after the second day. After four days the cultures of this fungus failed to produce colonies on plating out.

From these results it appears that, in three of the six fungi used, chlamydo-spores were produced in response to an adverse environment, being absent under favourable cultural conditions. Morphological features of this type have been reported to develop under sub-optimal conditions by other workers. Elliott† noted a darkening and a nodular development on fungal hyphae growing in the presence of bacterial contamination. Koch‡ observed that chlamydo-spores were formed by *Dibotryon morbosum* on potato-dextrose agar only near certain other organisms, one of which has since been shown to produce an antibiotic, or when toxic inorganic salts were added to the culture. In the present study the development of chlamydo-spores was associated with the ability to remain viable under conditions lethal to fungi lacking the capacity of producing them. Venkat Ram§ found that certain bacteria stimulate chlamydo-spore formation in *Fusarium solani*. He suggested that the phenomenon was due to the production of antibiotics by the bacteria and that it might be of importance in the survival of *Fusaria* in soils. Of the three fungi here found to have the capacity of producing chlamydo-spores, *Trichoderma* and *Stemphylium* were freshly isolated from soil. The remaining four fungi had been subcultured on agar for a number of years. It is suggested that the ability to produce resistant chlamydo-spores under adverse conditions, by extending the period of survival of a fungus in soil, may increase the probability of isolation of the fungus from soil. Thus strains possessing this ability will have a greater chance of being classified as members of the soil microflora.

I wish to express my thanks to Prof. O. W. Wardlaw, under whose supervision this work was carried out.

Shot-hole Disease of Stone Fruits caused by *Clasterosporium carpophilum*

PURE cultures of the fungus *Clasterosporium carpophilum* were isolated from recent infections of peach leaves and fruits. Isolation trials showed that the fungus is viable in leaf lesions from March until September. For this purpose, infected parts were washed thoroughly in sterile water and small portions of the diseased tissues were placed on corn-meal agar at 25° C. Hyphal tips were taken from the edge of the growing colonies and these were left to grow on corn-meal slants. In some cases, infected portions were sterilized using, first, 1 per cent silver nitrate solution for two minutes and then sodium chloride for 3-4 minutes and then washing thoroughly in sterile water.

Pathogenicity tests gave successful results by inoculating young peach seedlings (with 8-10 leaves) with a spore suspension of the fungus. Pricking the leaves was essential for getting clear symptoms in a week's time. High humidity was secured by covering the inoculated plants with bell-jars for three days after infection.

The rate of disease-spread was studied in the field. It was shown that the symptoms begin to appear in March (after leaf growth), the severity of the disease rises gradually until May, slows down slightly until September and then rises gradually until the end of the season.

The disease starts more severely in March after wet winters than after dry ones.

Control measures by spraying with Bordeaux mixture 4:6:60 or 4:6:100 at flowering time and at setting of fruits were not successful; neither was spraying with 20 or 10 per cent lime-sulphur at the above spraying dates.

A Variable Morphological Character of *Trichomonas vaginalis*

SEVERAL comprehensive morphological studies of *Trichomonas vaginalis* have been published¹. In none is mention made of a striking morphological character I have observed in three different strains of *T. vaginalis*. These strains were originally isolated from vaginal material gathered at the Whitechapel Clinic from patients with vaginitis and are now growing on artificial culture media².

The character takes the form of a variable thickening and rigidity of the terminal one-fourth to one-third of one of the four anterior flagella (Fig. 1). The presence and conspicuousness of this club-like structure varies between strains and between individuals in the same strain. It is conspicuous in most individuals in the W-2 strain, where it was first noticed; conspicuous but somewhat less frequent in the W-1 strain; least frequent in the W-3 strain. In the fourth strain, obtained from Dr. M. G. McEntegart, of the Liverpool City Laboratories, and which has now been in artificial culture for more than two years, the character appears to be absent.

Fig. 1. Clubbed flagellum of *Trichomonas vaginalis* in an active organism

Between individuals, the character varies in conspicuousness from a well-defined rod, about two to three times the diameter of the ordinary flagellum, down to a thin structure which is the same diameter as the rest of the flagellum and is manifested solely by its inflexibility. Characteristically, a single clubbed flagellum is found on an organism. In many individuals it is absent or undetectable; rarely two clubbed flagella are found in a single set of four, but never more than two.

In dividing forms with two sets of flagella I have found several combinations of the clubbing feature: one club in each set of flagella; a clubbed flagellum in one set only; apparent absence of clubbing in both sets.

While it can be observed in those dead organisms in which the flagella are not obscured, clubbing is best seen in the living organism. A 43 × objective with a 10 × eyepiece (or 5 × for greater depth of focus) make a good combination for detecting the character. It is most striking in dark-field preparations, in which the clubbed portion of the flagellum appears brightly luminous.

The clubbed structure was also found in a fresh vaginal specimen. Though difficult to observe because of the large amount of obscuring tissue debris and the extremely active state of the flagella, clubs were present in a small number of the organisms. The structure is not, therefore, a variation arising in artificial culture, but is an intrinsic, if variable, morphological character of *T. vaginalis*.

The function of the club-like flagellar structure of *T. vaginalis* is, at this stage, open to conjecture. Thickening of the tip of a flagellum has been noted in *Leptomonas ctenocephali*³, in which the enlargement is slimy in character and serves as an organ of attachment. The flagellar club of *T. vaginalis*, however, does not appear to be slimy or sticky. Another difference between the two is that in *L. ctenocephali* the thickened flagellum is much shortened, whereas in *T. vaginalis* the clubbed flagellum is never shorter, and at times appears to be longer, than its three associated flagella.

These preliminary observations are recorded to bring this hitherto unreported character of *T. vaginalis* to the notice of protozoal morphologists as a possible additional distinguishing character for the species.

I am indebted to Dr. A. J. King, senior physician of the Whitechapel Clinic, London Hospital, for permission to obtain clinical specimens. Miss Ann Laffy made the drawing.

ROYAL INSTITUTE (at 21 Albemarle Street, London, W.1), at 9 p.m.—Mr. Hayne Constant, F.R.S.: "The Search for Lightness".

Saturday, March 13

NUTRITION SOCIETY (at University College Hospital Medical School, University Street, London, W.O.1), at 10.30 a.m.—Symposium on "Some Problems of Nutrition".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT (with good training in bacteriology and an appropriate qualification, and preferably with experience in the dairy industry) IN THE BACTERIOLOGY DEPARTMENT, for work on bacterial spores in milk and general creamery hygiene—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting 54/2 (March 13).

ASSISTANT LECTURER IN AGRICULTURAL ECONOMICS—The Registrar, The University, Leeds 2 (March 13).

LECTURER, Grade II, IN MATHEMATICS, at University College, Ibadan, Nigeria—The Secretary, Inter-University Council, 1 Gordon Square, London, W.O.1 (March 15).

LECTURER IN MATHEMATICS at Fourth Bay College, Sierra Leone (University of Durham)—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.O.1 (March 15).

RESEARCH FELLOW IN CHEMISTRY—The Registrar, University College, Singleton Park, Swansea (March 15).

RESEARCH FELLOW IN METALLURGY—The Registrar, The University, Sheffield (March 15).

SENIOR LECTURER or LECTURER (Grade A) IN MATHEMATICS, SENIOR LECTURER or LECTURER (Grade A) IN PHYSICS, and a LECTURER (Grade A) IN BOTANY, at Kumasi College of Technology, Gold Coast—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.O.1 (March 22).

LECTURER (with a good honours degree and some relevant experience, preferably in the fields of reinforced concrete, soil machines or surveying) IN THE DEPARTMENT OF CIVIL ENGINEERING—The Registrar, The University, Bristol 8 (March 24).

LECTURER (with special qualifications in physical chemistry) IN CHEMISTRY, and a LECTURER (with special qualifications in organic chemistry) IN CHEMISTRY—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (March 27).

SCIENTIST (with a good honours degree or equivalent, and preferably with general experience in coal chemistry and spectroscopic techniques) for work in connexion with infra-red and ultra-violet spectroscopy—The National Coal Board, Central Research Establishment, Stoke Orchard, near Cheltenham, Glos., quoting TTF/746 (March 27).

TUTOR (honours graduate in science) IN THE DEPARTMENT OF EXTRA-MURAL EDUCATION, University of Glasgow, for duties which will consist mainly of conducting and organizing classes in adult education—The Director of Extra-mural Studies, 91 Oakfield Avenue, Glasgow, W.3 (March 29).

LECTURER IN GEOGRAPHY—The Secretary, Queen's University, Belfast (March 31).

SENIOR LECTURER IN INORGANIC AND PHYSICAL CHEMISTRY at the University of Adelaide, Adelaide, South Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.O.1 (Adelaide, March 31).

LECTURER IN BACTERIOLOGY at the Western Infirmary, Glasgow—The Secretary of University Court, The University, Glasgow (April 3).

VIROLOGIST (honours graduate, with qualifications in plant pathology, and preferably with postgraduate experience in methods of plant virus research) AT THE SCOTCH PLANT BREEDING STATION—The Secretary, Scottish Society for Research in Plant Breeding, Craig House, Comstock, Edinburgh 12 (April 3).

LECTURER IN APPLIED MATHEMATICS—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (April 17).

ENGINEERS and PHYSICISTS, Senior Scientific Officer and Scientific Officer grades (with an appropriate first- or second-class honours degree, or equivalent high professional attainments) in Royal Naval Scientific Service Experimental Establishments in the London, Portsmouth, Weymouth and Gloucestershire areas, and Scotland—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.245/54/A/R.5.

JUNIOR RESEARCH FELLOW IN MATHEMATICS or some branch of the PHYSICAL or BIOLOGICAL SCIENCES—The College Secretary, Balliol College, Oxford.

LECTURER (preferably with a knowledge of agricultural subjects) IN NUTRITION—The Secretary, Queen Elizabeth College, Campden Hill Road, London, W.8.

MASTER TO TEACH CHEMISTRY at least to advanced level with subsidiary Physics or Mathematics—The Headmaster, Westminster School, 17 Dean's Yard, London, S.W.1.

MASTER TO TEACH MATHEMATICS up to scholarship standard—The Headmaster, Wrekin College, Wellington, Shropshire.

SCIENTIFIC OFFICER (with an honours degree in science, preferably physics, and with experience in meteorology) at the Royal Observatory, Hong Kong, for forecasting, research, etc.—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting ODB 57/51/03.

SENIOR EXPERIMENTAL OFFICER (with at least H.S.C. (including physics), or equivalent, but preferably with a degree in physics) to be responsible for the organization and supervision of operations involving the processing of active materials; and for the accounting and movement control of active materials used by a research and development group—The Administrative Officer, Recruitment, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting 20/W.G.H.

SENIOR EXPERIMENTAL OFFICER or EXPERIMENTAL OFFICER (with at least H.S.C. (science) or equivalent, but preferably with a pass degree in science) for chemical engineering calculations, design and specification writing—The Administrative Officer, Recruitment, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting 19/W.G.H.

SENIOR SCIENTIFIC OFFICER or SCIENTIFIC OFFICER (with an honours degree in physics or electrical engineering or equivalent, and a detailed knowledge of ultra high-speed pulse techniques, and able to carry out design, development and engineering of special instruments using such techniques) at the Atomic Weapons Research Establishment, Fort Halstead—The Administrative Officer, Recruitment, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting 22/W.G.H.

FLUORITE OBJECTIVES

× 50 (1/7 in.) Oil immersion N.A. 0.95
× 100 (1/12 in.) Oil immersion N.A. 1.30

These new computations of outstanding merit are designed to be used with the NON-DRYING OIL supplied by us.

Compensating eyepieces × 6 and × 8 are available and should be employed to exploit fully the capabilities of these fine lenses.

Each objective is tested on the BAKER OBJECTIVE-TESTING INTERFEROMETER and only the finest selected material is used in manufacture.

FREELY SUSPENDED REFLECTING GALVANOMETER

A long period instrument suitable for ballistic measurements, or for sensitive current measurements when critically damped. Fitted with a spirit level, three levelling feet, coil clamping device, plane mirror and lens window of 1 metre working distance. (7940 to 7943—7 second period; 7944—9 second period.)

TWO SHILLINGS

THE *Newton*

LONG WORKING DISTANCE ATTACHMENT

... provides a working distance of 12.8 mm. between object glass and specimen when fitted to a standard microscope in conjunction with a conventional 4 or 8 mm. objective.

A further important feature is that the use of this attachment eliminates image reversal and thus further facilitates examination and manipulation of specimens.

STANDARD CADMIUM CELLS

Single and double types in wooden cases or in metal cases as illustrated.

Reliable single or double miniature types mounted in plastic cases, E.M.F. 1.01859 abs. volts at 20° C. Temp. coeff. $-40 \mu\text{V}/1^\circ \text{C}$. Low internal resistance. Dimensions $3\frac{1}{2}$ in. $\times$ $1\frac{1}{2}$ in. $\times$ $1\frac{1}{8}$ in.

Non-temperature coefficient cells for industrial use.

All types of unmounted standard cells can be supplied in quantity from stock.

• A NEW AND IMPORTANT ADVANCE IN MICROSCOPY

The Interference Microscope represents the very latest development in microscopical optics. Already researches utilizing the new instrument have been published in *Nature* and elsewhere.

In monochromatic light the images obtained are similar to phase-contrast images, but with continuously variable phase-change adjustment and a considerably greater sensitivity. The optical artifacts associated with phase-contrast are noticeably absent; whilst in white light the images are seen in colour contrast. The instrument is easy to set up and to adjust.

The microscope enables small phase-changes, under good conditions down to $1/300$ wavelength, to be measured. From these phase-change measurements the dry-mass of cells and other microscopical bodies can be calculated and refractive indices determined.

The Interference Microscope, in either double-focus or shearing form, is now available for delivery; please forward enquiries to

SPEED UP large-scale production with this research coating unit

Evaporation or sputtering of H.F. quartz crystals with frequency control.

Anti-reflection and interference films of all types for optical instruments. Metallizing plastic mouldings, small mirrors, etc.

Shadow-casting for electron and visual microscopy. Preparing thin films for electron diffraction investigation.

If you require to deposit thin metallic films for experimental, decorative or functional purposes, or wish to try out new production ideas, solve production snags and problems under the same working conditions as the industrial plant, this miniature pre-production research unit is the perfect answer—it REALLY is an extremely versatile high vacuum tool.

PHILIPS X-ray Diffraction Unit

This apparatus constitutes the ideal flexible diffraction machine. With a power unit rated at 60 kvp. 20 ma. any of the modern techniques can be readily employed. Among the many applications for this machine are:-

CHEMICAL IDENTIFICATION • PHASE ANALYSIS • SOLID SOLUBILITY STUDY • SINGLE CRYSTAL STUDIES • PARTICLE SIZE MEASUREMENTS
METALLOGRAPHIC STUDIES • MOLECULAR WEIGHT DETERMINATION
STRUCTURE IDENTIFICATION • STRESS ANALYSIS • FIBRE STUDIES
- PROCESS CONTROL • ORIENTATION STUDIES

PRECISION MADE • GENEROUSLY RATED • ALWAYS READY FOR US.

Triphenyl Phosphite

is a chemical for which several interesting uses have been established. For example, in the manufacture of alkyd resins and other paint media, it gives products of superior colour and clarity. Another application is in the preparation of alkyl halides difficult to prepare by more orthodox methods. Triphenyl Phosphite has been suggested as an oil additive, a fireproofing agent for natural and synthetic fibres and a termite repellent. Triphenyl Phosphite, a pale straw coloured liquid, is now available in commercial quantities.

Lens Measure

This instrument shows the surface curvature of optically worked glass surfaces and is mostly used on spectacle lenses.

It is calibrated in dioptric power, i.e., the receptical focal length expressed in metres assuming $\mu = 1.523$.

The Berwick is inexpensive, reliable and it gives clear, unmis-
takeable readings on a

two-colour dial. It contains only three moving parts and is particularly robust.

The 'glass' is unbreakable and the instrument is chrome plated and sold complete in cardboard box.

No. 915. Berwick Lens Measure.

List No. 155 describing this available on request.

Manufactured by

GOWLLANDS LTD

MORLAND ROAD, CROYDON.

DEVELOPMENT OF ATOMIC ENERGY IN BRITAIN

THE Atomic Energy Authority Bill follows the lines foreshadowed in the White Paper and in the long statement of the Government's policy which Lord Salisbury made on December 14. The Authority will consist of a chairman and not less than six or more than ten members, all appointed by the Lord President of the Council, whose responsibilities in regard to the Authority are clearly defined, and three of the members are to be persons with wide experience and proved capacity in dealing with problems associated with atomic energy. From the appointed day the Authority will be empowered to produce, use and dispose of atomic energy and to carry out research into any related subject, as well as to manufacture or handle other products required for such purposes. It will also arrange with universities and other institutions or persons for the conduct of research in atomic energy or radioactive substances, and with the approval of the Lord President of the Council and the Treasury, make grants or loans for production or research into matters connected with atomic energy or radioactive substances. Moreover, though the Authority is not, save under arrangement with the Minister of Supply, to develop or produce weapons or parts of weapons, it is explicitly free to conduct experimental work which may lead to improved types of explosive nuclear assemblies for atomic weapons.

The Authority is further empowered to distribute information relating to, and to train persons in, matters connected with atomic energy or radioactive substances. This clause to some extent appears to contemplate the Authority functioning as a training ground for the technical experts which industry will require when the industrial application of nuclear power becomes imminent. Apart from this, although the Authority to be established by the Bill is very clearly a manufacturing organization, with a degree of autonomy at least comparable to that enjoyed by other public corporations, and very considerable powers of direction for the technologists, and not as the Atomic Energy Commission of the United States, a co-ordinating body, the Bill makes even less reference to the co-operation of industry than did the White Paper. There appears to be no intention of permitting private industry to gain the all-important experience of helping with the design or operating of the key industrial plants which the Authority will control.

It would appear to fall within the powers and duties of the Lord President of the Council to give appropriate directions if at any time they should be deemed desirable. The Atomic Energy Act, 1946, already places on the Lord President the general duty of promoting and controlling the development of atomic energy, and the present Bill specifies that this duty shall include that of seeing that the Authority attaches the proper degrees of importance to the various applications of atomic energy. The Lord President may give general or particular directions after consultation with the Authority, but

is not expected to interfere in detail unless in his opinion over-riding national interests necessitate intervention. Furthermore, the powers of the Lord President, as defined in this section of the Bill, place on him the ultimate responsibility for deciding how wide and effective public discussion in this field can be by the extent to which he permits publication of the Authority's annual report.

That much was confirmed by the Minister of Works, Sir David Eccles, in moving the second reading of the Bill in the House of Commons on March 1. Sir David also referred particularly to the transfer proposed in the Bill of the powers in the Atomic Energy Act, 1946, and the Radioactive Substances Act, 1948, which relates to research, development and disposal of radioactive substances, from the Lord President to the Atomic Energy Authority. This step followed the transfer of Ministerial responsibility for atomic energy from the Minister of Supply to the Lord President of the Council, to which Parliament agreed last December. Sir David also indicated that the Lord President proposed to invite Sir John Cockcroft, Sir Christopher Hinton and Sir William Penney to be founder-members of the Authority, while continuing their executive responsibilities in sections of the Authority's work. He also stated that it had been decided to build a big, fast reactor of the 'breeder' type at Dounreay in Caithness, where survey work had already begun.

The magnitude of the responsibilities for Government policy in scientific and technological matters is made unmistakable by the Bill. Whether in fact they make impossible demands upon any one man, with his office as at present constituted, may be open to discussion. It should at least be impossible for the Lord President ever again to be saddled with extraneous departmental responsibilities, even through Ministerial sickness, and the practicability of the co-ordination of our scientific and technological effort and the disposition of the immense material resources involved in the organizations for which he is now responsible should be a central point in Parliamentary discussions on the Bill. Experience may well show whether or not some of the details of the proposed arrangements are sound, nor should it be difficult to modify them if necessary. What is all-important is effective informed public discussion of the fundamental issues involved in committing our resources on this scale.

Within the limits possible, the Atomic Scientists' Association has done much in recent months to bring to public discussion some of those questions. Others have been discussed in the United States in a series of issues of the *Bulletin of the Atomic Scientists*, which in the past year has repeatedly examined not only the security issue and its implications but also the place of private enterprise in the development of atomic energy. The Atomic Energy Commission in the United States has in fact already committed itself to the greater participation of industry, even to the extent of ownership and operation of nuclear power units and a more liberal policy in regard to patent rights. A recent (November

1953) issue of the *Annals of the American Academy of Political and Social Science* also explores in a series of articles not only such issues but also other implications of the impact of atomic energy, in the political and the industrial fields and on society in general.

The changes now proposed for Great Britain require, indeed, consideration in the widest context, not only in the light of the implications for our scientific and technical effort and resources, whether of man-power or materials, but also in the light of the effects upon our political institutions and the whole structure of society. It is perhaps even yet not fully appreciated how far secrecy has undermined the functioning of the democratic institutions by hindering the process of public understanding and control. The Government's decision to join the European Nuclear Research Organization is clearly right, as Lord Salisbury said at the anniversary dinner of the Royal Society, but less for the possibility of economy of material resources in such research, to which Lord Salisbury referred, than for the reason indicated by Dr. E. D. Adrian—the prospect of a speedier contraction of the area of secrecy.

The whole trend of Sir David Eccles's speech suggests that the Government is well aware of the importance of extending the area of public discussion as far as possible. There was no need, he said, to develop the peaceful uses of fissile material in the dark. It was intended that the Authority should have more liberty to let the outside world know what it was doing. Parliament and industry ought now to know what was going on, and, while he stressed the need for a strict security system, it was in the context that, unless there was mutual confidence in the effectiveness of security systems which guard information of such value to a potential enemy, we could not expect the essential exchange of information on the knowledge and practice of atomic weapons between members of the North Atlantic Treaty Organization. The finance of atomic energy, he admitted, was bound to be a trifle unruly and it was particularly difficult to estimate in advance how much new development would cost in any one financial year.

It should at least be recognized that the change now proposed will for the first time give Parliament some idea of the magnitude of expenditure in this field. According to Sir David, over the six years 1946–51, this exceeded £100 millions, and the Vote on Account now gives it as more than £50 millions a year, a figure which Sir David said would rise. Furthermore, although the proposals as set forth in the White Paper and in the Bill are open to the criticism that they give little indication as to how the all-important close contact and co-operation with industry are to be fostered, Sir David emphasized the Government's intention that, when a civil application of atomic energy reached the commercial stage, industry should take over, and he regarded expansion on the industrial side as a conclusive argument for the organization outside the Civil Service now proposed. Only under such an organization as is now proposed could we

hope to secure the drive and initiative, the speed and flexibility which would enable our scientists and engineers to develop fully this new source of power.

This vital factor of speed and initiative was missed by Opposition speakers in the debate, who seemed more intent on scoring party points than on constructive criticism or hammering out an agreed policy from the fundamental issues. Nor did two further important points made by Sir David receive comment. Referring to the placing of research contracts with universities and with industry, he said that the Authority would consider the education of outside scientists and engineers to be a very important part of its task. Further, following the example of the United States Atomic Energy Commission, a school of reactor technology was being set up where engineers from industry could learn about the fundamental principles of reactor design and be brought up against the many technical problems which designers have to solve.

The Government would do well to consider how far it can go within the framework envisaged by the White Paper, to make arrangements which will encourage confidence and facilitate discussion over the widest possible area of the scientific and technological effort of Great Britain. Something, of course, will depend on the appointments made to the additional posts to be created.

There are many problems on which no doubt the Government, and possibly the Waverley Committee itself, has reached no decision, and some may require time for solution. Some at least will be solved more readily by public discussion, and the Government should make it clear that there is to be no secrecy for secrecy's sake, even if in some matters care must be taken not to prejudice the fairer prospects for the Anglo-American exchange of information on atomic energy or other possibilities of Anglo-American co-operation. Neither science nor industry, however, must be held at arm's length. Frankness and confidence and full discussion within the practicable limits, generously interpreted, are the surest means of securing the co-operation of industry and of science, as they are of recruiting to the service of the Authority men of the ability and integrity required to discharge its great responsibilities with vision and energy, and to operate with skill, resource and decision.

There is this much to be added. The decision, for which there is a large measure of political agreement, to transfer to a public corporation the responsibility for the development of atomic energy must not be taken to imply that Britain is about to enjoy the benefits of nuclear fission, either for the production of power or for those other industrial purposes at which Sir John Cockcroft hinted in his Dalton Lecture on November 27. Even if the present hopes of the thermal reactors and the breeder reactor are fully realized, the application of nuclear power is still highly speculative, and much research and objective thought will be required if it is to bring advantage even to a nation placed such as Britain is in regard to fuel supplies. Isard and Whitney's recent study, while disposing of some exaggerated

ideas of the benefits which nuclear power could bring to underdeveloped areas lacking in power resources, and of the industrial disturbance likely to be caused by the adoption of nuclear energy as a source of power, left no doubt that the right decisions should be made objectively and on a factual basis*.

Their argument receives powerful support in the papers on the economic or sociological consequences of nuclear power and those on human values in the atomic age contributed to the symposium of the American Academy of Political and Social Science (*Annals*, 290; Nov. 1953), while the danger of allowing the development of atomic energy to become a party political issue can be seen in a paper by E. Douvan and S. B. Withey in the same symposium. To urge that the development of atomic energy should not be allowed to become a political issue, because there is considerable agreement that it should be entrusted to a public body subject only to broad Government control of policy and objectives, is not to suggest that the details of organization or of accountability have yet been settled, let alone agreed. It is rather to urge that those details, and above all the question of accountability, are most likely to find a satisfactory solution through an impartial, objective, all-party approach such as characterized the last debate on the nationalized industries in the House of Commons. An agreed solution of this vital question of accountability on such lines would have decisive advantages. It would give the proposed Corporation a standing which would command the confidence alike of scientist and technologist of the highest ability, whose services the Corporation must seek to enlist, and of industrial firms of repute and resources to which the Corporation could wisely entrust the development of reactors or fission products. It would, by removing the temptation to make party political capital out of minor points of difference over organization, and encouraging confidence in the effectiveness of public accountability, help any Government in power, independent of its political character, to maintain the wide and steady support from public funds which any enterprise of this kind requires before any return can be expected. Further, the support demanded for effective return, whether in defence or elsewhere, is on a scale which may well restrict the resources which can be apportioned to the social services or other sections of the national economy. The Government clearly can lead the way by making the area of public discussion as wide as possible, and putting the narrowest limits on secrecy that a realistic view of security permits; and the Opposition must respond in order to take the whole question out of the arena of politics. Grave indeed will be the responsibility of any who hinder accord and disturb the process of critical but objective inquiry and mutual understanding, upon which depend the ability of the new Corporation to recruit staff of the requisite calibre, to secure the co-operation of responsible industry and to provide the nation with whatever benefits the application of nuclear energy or fission products can bring.

Company, Ltd., 1953.) 140s.

History of Strength of Materials

With a brief account of the History of Theory of
Elasticity and Theory of Structures. By Prof.
Stephen P. Timoshenko. Pp. x+452. (London:
McGraw-Hill Publishing Company, Ltd., 1953.)
71s. 6d.

STEPHEN PROKOFIEVITCH TIMOSHENKO
was born on December 22, 1878. Few men have
suffered more interruption of their scientific work by
war and revolution, yet few have had greater
influence or, when they attained the age of seventy-
five, a wider circle of devoted friends to join in
birthday greetings. Six who have been associated
with him longest have produced, to celebrate the
anniversary, a volume containing all his papers
except a few in Russian never republished elsewhere,
along with an admirable photograph and a bio-
graphical preface. It appears almost simultaneously
(and in identical format) with his own monumental
"History of Strength of Materials": an amplification
of lectures given in the past twenty-five years, of
which the first chapter starts from the birth of
Galileo, the last takes the story down to 1950.
Together the books comprise more than a thousand
pages—too much material for a detailed review.

By his friends they will be studied in conjunction,
for the light they throw on the development of his
thought; more particularly the last two chapters
of the "History", in conjunction with Prof. D. H.
Young's "short biographical sketch". They cover
the first half of the present century: years in which
Klein, Runge, Prandtl and von Kármán increased
yet further the fame that Gauss, Dirichlet, Riemann
and Clebsch had brought to the University of
Göttingen. It was there, in 1906, that Timoshenko
met Klein's innovation of seminars attended both by
engineers and mathematicians; there, that at the
suggestion of Ludwig Prandtl he began the study of
what has been his prime interest ever since—the
theory of elastic instability. As it happened, in the
two preceding years he had read Love's "Elasticity"
and Rayleigh's "Sound" ("Such was the subject-
matter by which he taught himself to read English"),
and his first paper, published in 1905 (in Russian),
reveals the immense impression Rayleigh's work had
made on him. In it—for the first time, probably—a
man discussed elastic instability who realized that
"Rayleigh's method", though propounded in relation
to vibrating systems, is applicable to physically
distinct problems. Somewhat later (1909) Ritz had
extended it by largely increasing the number of the
variable parameters; and his work, too, made a great
impression on Timoshenko, shown by the reference
to it in the French version (1913) of his big memoir
of 1910 (in German)—so great an impression, that
almost invariably he has termed the extended method
the "method of Rayleigh-Ritz". It may well be that
Ritz hit on it independently, for his first paper
called it a "new method for the solution of variational
problems"; but I confess to being, with Rayleigh
("Collected Papers", 6, p. 48), "surprised that he
should have regarded the method itself as new. . .".
(Referring to his own "Theory of Sound", Rayleigh
continued: "I had supposed that this treatise
abounded in applications of the method. . ."; and

added, "in a more recent paper [1899] . . . it takes
almost exactly the shape employed by Ritz".)

For me it has been of absorbing interest to read
of events preceding those of which I learned some-
thing at the time, in letters from Timoshenko relating
to scientific publication. Though given an intro-
duction in 1918 (by Bertram Hopkinson) I did not
meet him in person until 1921; by then he had
become a professor in Zagreb, and had sent me from
there a paper which appeared in the *Philosophical
Magazine* of May 1921. Other papers followed during
1922, in which year he passed through London on
his way to his first post in the United States. He
did not (I think) contribute to the First Congress of
Applied Mechanics at Delft in 1924—the year in
which his first book was published in the United
States—but read two papers (both now reproduced)
at the Second Congress in Zurich (1926). In 1927 he
re-entered academic life as professor of graduate
mechanics in the University of Michigan, and there
began to exert on engineering education an influence
which by now is quite unparalleled: by lectures,
seminars and summer schools, and above all by the
text-books which have made his fame world-wide.

They are used everywhere, and in large measure
they remove the need for students to study his
original papers; but all will turn to his "History"
who have heard his lectures and recall their out-
standing quality of erudition. For many books have
been written on strength of materials, but few that
show even an interest in the man that have developed
it. Inevitably, in a work so comprehensive, some
pronouncements will seem questionable, some omis-
sions hard to understand; and I for one was sur-
prised to find no account of work by Baker's school
at Cambridge and Prager's at Brown University on
'limit design' of steel structures with rigid joints, no
mention—in a survey which includes experiment—
of Bridgman's work with very high pressures or of
the work of Cook and Robertson which revealed, in
mild steel, the 'drop of stress at yield'. But these
are but incidental criticisms, and what remains
from a reading as yet only cursory is delighted
amazement at the sweep and vigour of one man's
handling of so vast a theme. Many footnotes will
need revision when the "History" has been
assimilated.

R. V. SOUTHWELL

INTRODUCTION TO PILE NEUTRON RESEARCH

Pile Neutron Research

By Prof. D. J. Hughes. (Addison-Wesley Nuclear
Science and Engineering Series.) Pp. xiii+386.
(Cambridge, Mass.: Addison-Wesley Publishing Co.,
Inc., 1953.) 8.50 dollars.

THE first chain-reacting pile became critical in
December 1942, and during the decade following
that event the pile has been extensively used as a
neutron source. A new technology has grown up
with the development of 'pile neutron research', and
as the numbers working in this field increase it has
become a pressing need to have a basic text-book for
the subject. This need is met by this book by Prof.
D. J. Hughes. It is the nature—and the weakness—
of the book to describe the work that has been done
without reviewing it critically.

As is proper in dealing with a new subject, a great
deal of the material is presented at an elementary

level, but in most cases references are given which would enable a particular subject to be taken further. The author classifies his material (apart from the chapters on neutron optics) according to the type of pile facility required, and this enables him to place the wide diversity of the objects of pile neutron experiments into reasonable order. Some of the illustrative experiments (for example, those on neutron mirrors) are given in great detail, presumably because this will familiarize the student with some of the difficulties of careful and accurate measurements with the pile. However, Prof. Hughes does not stress this point. It is inevitable that, as a new field is developed, systematic errors should be present in some of the early measurements because some of the factors which influence the results are overlooked. A striking illustration of this is the frequent disagreement of various cross-section measurements (for example, the total cross-sections of boron and gold). At the present stage in the development of this new technology, it is important that a very critical approach should be made to every measurement, and that normally the experimental error quoted should be treated with reserve. This point should have been emphasized throughout the book.

A good basic introduction to the neutron and to reactors is given in the first two chapters. A practical point of some importance which is not mentioned here is the movement of the flux distribution in the pile as the control rods are moved. This is one of the reasons why separate monitoring of the intensity in beam experiments is desirable. In Chapters 3-11 a complete account of the development of pile neutron research is found. Attention is focused upon the techniques rather than the theory, and for the latter the student is invited to study the references given. The point of interest is the behaviour of the neutrons of various velocity groups.

The principles behind most of the measurements are simple, but since it is difficult to obtain accurate results, it would have been useful (in a book on Technology) if Prof. Hughes had listed the precautions which had been taken in each experiment.

Of the various points discussed, those worth emphasizing are the uncertainties in the absolute determination of neutron intensities and cross-sections, and of the detail of neutron spectra. In beam experiments one needs to have reliable collimation of fast and slow neutrons and γ -rays, and to control, by careful shielding, backgrounds due to multiple scattering of neutrons. Considerable space is devoted to the discussion of filters, which are finding increasing use as ancillaries in more complicated equipment.

Occasionally, in the interests of simplicity the subject has been over-simplified. For example, the thermal inelastic scattering is stated to be incoherent, whereas it exhibits (particularly in the energy spectrum of the scattered neutrons) pronounced interference effects. Or, again, in the discussion of the resolution of time-of-flight spectrometers, it is tacitly assumed that the time uncertainty of the instrument is a constant, whereas in many cases the time-of-flight in the detector is appreciable, and this contribution to the resolution width is a function of neutron velocity. This means that to the table of resolution widths (Table 6-2) a definite velocity should be assigned.

The book concludes with a chapter on health physics. In many cases the question of the health hazard involved in an experiment must fall upon the

experimentalist; and it would be instructive to the student to read this chapter after Chapter 2 and before proceeding to the experimental sections. A useful course on pile physics and a table of thermal neutron cross-sections are found in appendices.

In all the branches of the subject discussed by Prof. Hughes, rapid advances are being made and very soon new techniques will be in use. In spite of this, this book will remain for some years a valuable introductory text. Prof. Hughes is to be congratulated on writing with such lucidity and detail on the many and varied aspects of pile neutron research.

P. A. ECKSTAFF

INORGANIC CHEMICAL ANALYSIS

Textbook of Quantitative Inorganic Analysis.

By Prof. I. M. Kolthoff and Prof. E. B. Sandell. Third edition. Pp. xv+789. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1952.) 30s. net.

Applied Inorganic Analysis

With Special Reference to the Analysis of Metals, Minerals and Rocks. By the late Dr. W. F. Hillebrand and the late Dr. G. E. F. Lundell. Second edition revised by Dr. G. E. F. Lundell, H. A. Bright, and Dr. J. I. Hoffman. Pp. xxii+1034. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953.) 120s. net.

THOUGH there is some overlap, these two new editions of well-known books are complementary.

In this, the third edition of their book, Profs. I. M. Kolthoff and E. B. Sandell adhere to their original purpose and provide a detailed treatment of the theoretical and practical aspects of many gravimetric, volumetric and physicochemical methods of chemical analysis; more modern developments, such as chromatography, mass spectrometry, Raman spectroscopy, fluorescence and other topics are reviewed, with adequate references to more detailed expositions. The book is intended for university students, but more experienced workers will find in it a useful summary of recent developments. As a practical reference work for the advanced or specialized worker, the book is less useful; for example, the section on gravimetric determinations deals in detail with only water, chlorine, iron, aluminium, sulphur, calcium, magnesium, phosphorus, silica, sodium, potassium, copper, nickel and limestone. One hastens to add that sections on brass, steel and silicate rocks, and numerous bibliographical references, greatly extend the scope of the book, and that throughout, when details are given, the treatment is thorough. In this thoroughly revised and modernized edition, sections rewritten or enlarged include those dealing with physical and physicochemical methods and with organic reagents.

The first edition of W. F. Hillebrand and G. E. F. Lundell's "Applied Inorganic Analysis" was published in 1929; because of its excellence and very reputable authors, the book was accepted as a standard work of reference. Though the original authors are now dead, Dr. Lundell wrote much of this new edition; his manuscript was reviewed and completed after his death by the two junior authors. The general arrangement of subject-matter in the old and new editions is substantially the same, the aim being to describe useful methods of separation and determination rather than to catalogue all

available methods, some of which may be useless for the analysis of complex substances.

For each element or group of elements, information is given concerning behaviour during the course of an 'ordinary' analysis, methods of decomposing minerals, methods of separation and methods of determination. The book has been brought up to date by appropriate omissions, additions and rewriting; special methods, such as those involving the use of the spectrograph, the polarograph, etc., receive attention, but are not described in detail. Some information is given about nearly all the chemical elements, the only elements not included being inappropriate ones, that is, the rare gases, actinium, polonium and the elements discovered during recent years. The section on the rare-earth metals contains much useful information concerning the more orthodox methods, but ion-exchange methods are not described in detail; however, this section, like all sections of the book, is adequately annotated with references to other publications. Similar comments apply to other parts of the book; as examples, the dithizone method for lead, and ether-extraction methods for the separation of uranium are not described in detail. In this edition, the sections dealing with glass, bauxite and refractories have been omitted, but the classical methods used by Dr. Hillebrand for rock and mineral analysis are retained, with necessary additions.

C. O. HARVEY

A MANUAL OF SCIENTIFIC AND INDUSTRIAL INSTRUMENTS

The Instrument Manual

Second edition. Pp. vii+628+105. (London: United Trade Press, Ltd., 1953.) 84s.

THE writing of an adverse review is always an unpleasant task, but the unpleasantness increases with the size and price of the book concerned; there seems to be an instinctive feeling that a large and expensive volume should be more reliable than a small, cheap one.

The second edition of the "Instrument Manual" is designed on a large and expensive scale; the idea behind it is excellent, but the result is sadly disappointing. The manual is divided into a series of chapters each of which deals with a particular type of measurement and consists of a theoretical introduction, descriptions of the instruments available, a list of manufacturers and a list of references to the literature. The field covered is very wide and the present reviewer can only comment with confidence on the detail of one or two of the chapters, but grossly misleading and erroneous statements found on familiar subjects undermine one's confidence in the remainder.

Perhaps examples from one of the more unfortunate sections might be quoted here (p. 56, Polarimetry): "Polarisation. To understand polarisation it is necessary to regard light as being a wave motion in more than one plane, e.g. there will be transverse vibrations as well as those in the direction of travel of the wave. The effect is indicated simply in Fig. OP 11. If it should be possible to remove one of these modes of vibration, the wave is said to have become plane polarised". The figure mentioned is said to represent a wave travelling along the x -axis of a system of co-ordinates and shows two sinusoidal waves, one along z and one along y , at right angles

to it. Later in the paragraph we find the statement: "If y becomes zero, the wave can be said to be plane polarised . . .". Towards the end of the following section we read: "If the plane polarised light emerging from a Nicol prism is allowed to fall on a second prism with its principal plane parallel to the first, the beam is split into two components, one of which, as in the first Nicol, is transmitted. If the second prism is rotated, it will be found that the intensity of the light decreases to a minimum when the principal planes are crossed at an angle of 90° . The intensity is thus *proportional to the angle of rotation*" (the italics are the reviewer's). These statements surely need no comment.

In addition to serious errors of this type, the book contains a large number of paragraphs which give no useful information at all and which might very well mislead a person with no previous knowledge of the instrument described. An example of this is the description of wet- and dry-bulb thermometers on p. 531. It is quoted in full: "These are mercury-in-glass thermometers in which the bulb is circular, and consist of the normal thermometer stem encased in an outer glass sheath, terminating at its upper end in a glass button for suspension purposes. The sheath not only protects the graduation against damage but prevents the condensation of moisture on the divisions or figures of the scale. At the lower end it is fused to the thermometer proper between the bulb and the lowest graduation". Such a description would certainly merit no marks at all in an examination at even the lowest level.

Some of the sections seem to be incomplete and lack continuity, as though they had been made up by stringing together the work of different writers and draughtsmen without proper co-ordination. For example, in a section of the chapter on temperature measurement headed "Black Body Radiation" (which, incidentally, begins "If a piece of carbon or charcoal (i.e. a black body) . . .") we find a diagram (p. 277) of a square enclosure labelled A with a ray, starting from wall C and being regularly reflected in turn from walls D , E and B . The whole paragraph relating to this figure runs as follows: "Accepting a black body condition as standard, it is desirable to achieve this as nearly as possible in actual instrumentation. Let us consider in Fig. T.T. 64 an enclosure A at a uniform temperature with a very small opening at B . The walls of the enclosure are of a material which partially absorbs and reflects radiation. A ray starting from wall C strikes wall D . Corrections may be necessary because of temperature gradient in the tube".

It would not serve any useful purpose to give any more detailed examples. One might summarize by stating that the book is reminiscent of an examination script sent in by a reasonably good student who, in his anxiety to impress the examiner, has written down all he knows regardless of its relevance to the question, putting in padding where his knowledge fails, occasionally going off the rails altogether, and certainly leaving no time for reading through at the end. In the stress of an examination this could be forgiven, but one scarcely expects it in the second, revised edition of a book costing four guineas.

There is undoubtedly a need for a book covering this ground and a great opportunity has been missed. Let us hope that if a third edition should be contemplated, the attention of the editors will be concentrated on putting right what is already there rather than on the addition of new material.

G. A. TAYLOR

THE PROCESS OF SONG-LEARNING IN THE CHAFFINCH AS STUDIED
BY MEANS OF THE SOUND SPECTROGRAPH

By Dr. W. H. THORPE, F.R.S.

Jesus College, Cambridge

IT has been known since the late seventeenth century¹ that the full song of some species of passerine birds shows considerable local variation in pattern; and there are many facts which point to the conclusion that some of this local variation is the expression of a 'learned tradition' and not, as most call notes seem to be, genetically fixed. Nevertheless, there is also very strong evidence with many other species that even the full songs may be primarily an expression of genetic constitution. So we get the puzzling situation that complex details of the full song may be completely inborn in many species, modifiable by learning in some and probably entirely learnt in yet others. It has been suggested that many of the apparently inborn 'recognitions'—as, for example, the visual recognition of the fellow member of the species—which play such an essential part in the organization of the social life of many animals are, in fact, acquired by a special type of learning known as imprinting, which is very rapid and the effects of which are extremely persistent. The process of song learning certainly resembles imprinting in several respects, and in any event the details of the interlacement of instinct and learning in situations such as that of song production are of interest from many points of view. This is especially true in that the restriction of learning ability to a particular period and particular circumstances is not a situation with which learning theorists are as yet very familiar; and indeed such a process raises interesting problems concerning the very nature of learning itself.

Until recently, it was scarcely possible to make much progress with the problem of song learning. Bird songs, like most other animal sounds, are difficult to describe in words, and even the most musical find it difficult to remember minute details of song without the aid of a suitable notation; so the dangers of subjective interpretation are always serious. But even if a satisfactory system of notation had been elaborated, there would still have remained the primary difficulty of perceiving accurately by the naked ear elaborate sound patterns of high frequency, high speed and rapid modulation. All this was changed, however, by the development on one hand of methods of high-fidelity 'electrical recording' on disk and of magnetic recording on tape, and on the other hand by the invention of the sound spectrograph, now known commercially as the 'Sonograph'. This latter instrument automatically provides a graphic analysis of complex sound signals that vary with time.

In operation, the sound which it is required to analyse is first recorded magnetically on the edge of a 12-in. metal disk. The disk is then revolved repeatedly at 3.3 times the recording speed, and at each repetition the signal is scanned by either a 45-cycle or a 300-cycle band-pass filter which is

shifted slightly in frequency at each repetition. The output of the analysing filter is then recorded on dry facsimile paper on a drum which revolves synchronously with the magnetic disk. The recording stylus shifts gradually along the frequency-scale in step with the scanning oscillator, thus recording the frequency components at any given instant, while amplitude fluctuations will be represented by fluctuations of intensity at the output of the filter and so will show up on the paper as lighter or darker areas—the darker regions being those of higher energy-level.

From this graphic representation, frequency, amplitude and duration can be determined with sufficient accuracy, and moreover the sound spectrogram can with practice be recognized and interpreted as a 'picture' of the sounds. It thus supplies a form of notation as well as a method of precise measurement. So it is that an entirely new field in behaviour study has been opened up, for whereas vocalizations were formerly the most difficult of all releases to investigate precisely, they have now become far more readily amenable to analysis than are many patterns of visual or olfactory stimulation. The object of the present article is to indicate some of the many possibilities of the method, and to give in preliminary outline some of the more important results so far achieved.

The method in the present study has been to record all the songs either on tape or disk, to subject them to rough preliminary 'inspection' by slowing down on re-play, and then to analyse them by transferring them to the sound spectrograph. The disk and tape machines used will deal faithfully with sounds from 50 to 12,000 cycles and from 50 to 17,000 cycles per second respectively, while the sonograph can also be adapted to deal directly or indirectly with the latter frequency-range. It has, in fact, transpired that for present purposes the range 2,000–10,000 cycles per sec. is all that need be taken into account. (For the first use of the 'Sonograph' I have been greatly indebted to the kindness and courtesy of the Superintendent and staff of the Admiralty Research Laboratory at Teddington, whose 'Sonograph' was for a long time the sole instrument of its kind in England. In particular, I would like to express my thanks to Mr. S. A. Byard and Mr. H. G. T. P. Risson. Latterly, through a generous benefaction, a new instrument has been provided specially for this and similar work at the Ornithological Field Station of the University of Cambridge Department of Zoology at Madingley. The sound spectrograms here reproduced have all been made with this new instrument.)

Work was commenced in 1950 with the inauguration of the above field station. Here was available for the first time the necessary equipment of breeding aviaries, bird-rooms for hand rearing and observa-

Fig. 1. Sound spectrograms of songs of control chaffinches in aviaries showing the three phrases. (a) *RWB/W*, April 20, 1953. (b) *BW/W*, May 18, 1953. (c) *BW/BEP*, March 25, 1953. Band-pass filter, 300 c./s.

tion, and sound-proof rooms for isolation experiments. The chaffinch (*Fringilla coelebs*) was chosen as the first and chief experimental species for several reasons: it has a complex and not too elaborate phrasical song of medium frequency-range and convenient length. Moreover, while the song is readily recognizable in its different forms, it is well known to have striking local peculiarities, songs of one type predominating in one area, those of another in an adjacent area³; and each individual normally sings only one type of song.

The normal chaffinch song, which is both a territorial proclamation and a stimulus to the female, consists of three phrases (Fig. 1). Phrase 1 consists of from four to fourteen notes, usually somewhat *crescendo* and normally with a gradual or step-wise decrease of mean frequency. This is followed by phrase 2, which is usually, but not always, distinct and is made up of a series of two to eight notes. These notes are of a fairly constant frequency, lower than that of phrase 1. The song concludes with a phrase 3 consisting of from one to five notes (phrase 3A), together with a more or less complex terminal flourish (phrase 3B).

In 1950 Poulsen⁴ described how two male chaffinches reared in isolation had produced songs which were abnormal in the pitch and rhythm of phrases

1 and 2, and in having a single note in place of the normal version of phrase 3B. He states that two other male birds which he caught as first-autumn juveniles also produced abnormal songs of this type. From observations of these four birds, he concluded that the chaffinch song has an inborn basis, but that the third part of the song and the pitch and rhythm of the first two parts have to be learnt. He also considered that the learning is due solely to imitation during a relatively short period of a few weeks in the early spring of their first year of adult life. It now seems clear that these conclusions need a good deal of modification.

The first step was, of course, to prove that rearing in aviaries and cages did not necessarily affect the song pattern. Thirty control birds have now been recorded in these circumstances, and so

we have a fairly precise picture of the 'normal song' (Fig. 1). The first series of experiments then consisted in taking birds which had been reared normally by their own parents, and isolating them from their first September onwards in order to study the development of their songs in the ensuing spring. It was soon found that it is not necessary for such birds to see other singing chaffinches in order to acquire normal songs. Even if such birds are caged with song birds of other species and so subject to an overwhelming 'barrage' of alien song, they can still attend only to the normal song of their species which they hear from the outside; and our experimental birds failed to show any sign of acquiring the alien songs to which they were exposed, though it is said that the chaffinch will sometimes incorporate the notes of other species in its sub-song⁵. In this lack of general imitation the chaffinch is in marked contrast with the bullfinch (*Pyrrhula pyrrhula*) and the greenfinch (*Chloris chloris*), which will learn complete songs from an alien species. In these experiments, seven chaffinches were exposed to canary song in the bird room, three to greenfinch song and two to goldfinch song in aviaries, without any abnormality resulting.

If such birds isolated as juveniles are kept out of hearing of all bird song from September until the

following May, but are allowed to hear vocalizations of other chaffinches treated in the same way, a clear difference is noticeable. Phrases 1 and 2 of the songs are practically normal, although they show much variation; but there is a slight tendency for the endings to be abnormal and to approximate to a community pattern. Twenty-seven birds were treated in this way and were isolated in six distinct groups. Fig. 2 shows the sound spectrograms of two genetically unrelated birds which have developed songs closely similar in ending as a result of being thus confined together. They are fairly representative of the general run of the experiments.

If we now repeat such an experiment using instead birds which have been hand-reared and have thus been isolated from contact with experienced birds since the first few days of nestling life, we get a very different result. Phrases 1 and 2 are now often inseparable, and phrase 3A is always lacking. Phrase 3B is often lacking also, or at most is represented by a single 'squeak' of fairly steady pitch though often of considerable frequency-range. Each isolated community of such birds builds up during the period February to April inclusive an entirely individual but extremely uniform community pattern, the resemblances throughout the song being so close that it is often very difficult to distinguish the songs of the different members of the group one from another even when subjected to a detailed analysis by the sound spectrograph. Figs. 3, 4 and 5 show the sound spectrograms of such groups of birds. The first pair (Fig. 3) were kept together in isolation during 1951-52 and had no contact with any other birds at all. The second pair (Figs. 4a and b) were similarly isolated 1952-53, while Fig. 5 shows the pattern produced by members of a group of five kept together in isolation during 1952-53. Inspection of the figures will show that the detailed resemblances are extraordinarily exact and concern all parts of the song, and the second of these song-types is quite unlike anything that has yet been recorded from the wild.

It appears, then, that the difference between the hand-reared birds and those which had a normal fledgling and early juvenile life, but which were isolated from September onwards, is only explicable on the assumption that some characteristics of the normal song have been learnt in the earliest youth before the bird itself is able to produce any kind of full song. It seems that these birds have by their first September learnt that the song should be in three phrases, and that the terminal phrase should contain a more-or-less elaborate flourish. The details of this terminal phrase with its flourish are apparently not learnt then but are worked out by competitive singing with other members of the group in the following spring.

Fig. 2 (a) and (b). Songs of two 1951 chaffinches (*BY/RWB* and *O/GF*) reared by their own parents but isolated as juveniles of five months and allowed only to hear the members of their own group of five birds identically treated during their critical song-learning period in 1952. Note very close resemblance of latter parts of song. (c) Song of *O/GF* in 1953, to show fifty of song in second year even though given opportunity to hear many varieties of chaffinch song in second season. These three songs can be regarded as 'normal'. Scales as in Fig. 1

The experiments with the hand-reared birds suggest that there is an inborn basis to the song but that it is extremely generalized. Innately these birds seem able to produce a song of about the normal length, 2.3 sec., and showing a tendency to *crescendo* accompanied by a fairly steady fall in mean frequency. There is no clear indication of any inborn division of the first part of the song into phrases 1 and 2, but there is a clear tendency in some birds to conclude the song with a single simple note of a higher pitch than the rest. They seem quite unable, by themselves, to produce anything more complex in the way of an ending although, as Fig. 5 shows, they can learn, by a process of mutual stimulation and imitation, to produce precisely controlled and highly elaborate song patterns in what corresponds to phrase 2 of the normal song. (While the present evidence points to the conclusion that these features of the songs produced by hand-reared birds are inborn, we must remember that it has not yet been possible to rear such birds in isolation in the sound-proof room right from the egg. Until this has been done, which we hope will be in the near future, the possibility cannot be ruled out that some details of the song are learnt by the nestling in the first few days after hatching, or even during the last hours in

Fig. 3 (a) and (b). Songs of two unrelated 1951 hand-reared chaffinches (*BY/PW* and *RWB/Y*) isolated from about the fourth day of life and during the critical learning period of their first season allowed only to hear each other's songs (Recorded April 1952). Note: Songs abnormal, relatively simple and closely similar. Phrase 3 lacking. Scales as in Fig. 1

the egg. That chaffinches which have been hand-reared can be taught full and elaborate end-phrases when kept during the following spring with older birds selected for their fine songs was known to the German bird fanciers well over a century ago*.)

Study of sound spectrograms makes it clear that it is the pattern of the song that is learnt and not its absolute pitch. One occasionally finds a bird practising a song ending *soho* vocs at a markedly different pitch from that in which it is rendered as part of the full song, and there are other examples of slight change in pitch with changes in intensity of motivation.

Once a song has been acquired and has been sung for a period of a few days at full intensity, it becomes fixed and subsequent changes are extremely slight.

The individual songs of fifteen different birds have now been recorded and analysed in two or more subsequent years, and in nearly every case the differences between the first and second year are so minute as to be practically imperceptible to the naked ear although they will show up on the spectrograph records. Figs. 2b and c show the songs of the same bird in 1952 and 1953. As Fig. 2c shows, a bird in its second year may retain char-

acteristic features in its song which involve a frequency change of a few hundred cycles or less and of only 10–20 msec. duration. Such slight changes that do occur involve small differences of emphasis and occasionally the alteration of a phrase or perhaps the omission of the repeat of a phrase which was doubled in the former year. The sound spectrograph has, however, unexpectedly provided evidence that there is a slight but almost uniform tendency for the song to be shorter, by about 0.1–0.3 sec., in the second year than in the first, and that there is also a slight tendency to increase the frequency-range in all phrases of the song. There is as yet no

clue why this should be so.

It is possible to delay the period of learning a song by keeping the birds together in aviaries under such conditions that they will not sing for the time being, although they see and hear normal birds singing. If such birds are transferred in the summer (that is, July) to a chamber where they are artificially subject first to a gradually decreasing day-length for about eight weeks and then, in early October, to an increasing day-length, their gonad growth will again be stimulated and they will be brought into full song in the autumn (October–November). During this period they show evidence of acquiring the song ending by learning in the same way that they would have done had they been allowed to sing in the spring. Birds can also be brought into song at any

Fig. 4 (a) and (b). Songs of two unrelated hand-reared chaffinches of 1953 (*RWB/W* and *GY/Y*) treated as those shown in Fig. 3. (Recorded June 1953.) Note: Phrases 1 and 2 elaborate but highly abnormal. Phrase 3 extremely simple. The two songs are identical in almost every respect. Scales as in Fig. 1

Fig. 5 Song typical of those produced by all members of a group of five 1953 hand-reared chaffinches treated exactly as those shown in Figs. 3 and 4. (SW² recorded June 1953.) Note: Abnormal song with extremely simple phrase 3 (2s. lacking). Scales as in Fig. 1

season of the year by injection with the hormone testosterone propionate. Songs induced by the light method or by hormone injection seem not to differ in any way from the normal.

Bird fanciers rearing these and other finches have long been familiar with the 'sub-song' which precedes the true song in the late winter or early spring. In the chaffinch, this sub-song consists of a long continued and rather irregular warbling which, as the day-length increases and the production of sex hormone (as indicated by the change in colour of the bill) rises, slowly gives place to the phrases of the true song. The process gives to the listener the impression of the true song, so to speak, 'crystallizing out' of the amorphous sub-song. While the sub-song is undoubtedly to some extent a product of the lower degrees of motivation, in that it occurs in the second and later years as well as the first, yet it is much more in evidence in the first and seems to play some part in the process of learning the full song. When studied by the sound spectrograph, the sub-song appears to have a much greater frequency-range than the true song, and one at least of the processes by which the sub-song is transformed into the true song consists of the gradual dropping out of the extreme frequencies which have no place in the latter. The whole matter of sub-song and its differing types and functions in different species is one which requires much more investigation and cannot be dealt with here. Such sub-songs are seldom noticed in the wild because of their low intensity, and also because the bird often sings in very close cover instead of from a conspicuous song post as when producing the true song. Nevertheless, though inconspicuous, the sub-song is, in the chaffinch, a significant feature in the process of song acquisition.

To summarize: We can at present conclude that the normal chaffinch song of three phrases has a very restricted inborn basis amounting to little more than the ability to produce a song of about the normal length (2.3 sec.) and consisting of a *crescendo* series concluded by a single note of relatively high 'pitch'. All further refinements have to be learnt; but the innate basis of the song is probably sufficiently selective to ensure that the bird does not normally acquire notes or songs from any species other than its own. Some learning of details of the first part of the song and also learning of the fact that the song 'should' end in a relatively complex terminal flourish (phrases 3A and B) can take place in the first weeks of life—before, of course, the bird itself is capable of singing. But during this time no details of phrase 3 are acquired. This last phrase, together with more refinement in the early part of the song, is acquired during a period of high learning ability lasting for a period of a few weeks in the bird's first spring, when

it is attempting for the first time to sing in competition with other chaffinches. This results in the development, in isolated groups of hand-reared birds, of distinct community patterns of song; and there is little doubt that the same process of 'imitation' results in the establishment in the wild of the local song 'traditions' which have so long been recognized in this species. There is some evidence that the 'sensitive period' can be delayed for some weeks by experimental treatment, and it sometimes happens

that a bird can at a later stage acquire a second song in addition to its first. The song, once acquired, is retained with little or no alteration in subsequent years. The learning is of a pattern independent of pitch, though the birds are able to maintain a constant pitch with great accuracy. Some references on the sound spectrograph are appended¹⁻³.

EXCITED NUCLEONS

By PROF. C. F. POWELL, F.R.S.

H. H. Wills Physical Laboratory, University of Bristol

DURING the past year, evidence has gradually accumulated for the existence of a new type of nuclear excitation which appears to be due to the presence, within a nucleus, of a neutral hyperon*, now designated Λ^0 . It is believed that this particle can be bound to the other nucleons of a nucleus to form a relatively stable structure as measured on a nuclear time-scale, and that the eventual disintegration of such a nucleus is due to the decay of the Λ^0 -particle.

The existence of the Λ^0 -particle, which until recently was referred to as the 'heavy neutral V -particle', was established by experiments on the cosmic radiation with Wilson chambers. It was shown to be the more common of the neutral particles which produce the 'neutral V -events' discovered by Rochester and Butler¹ in 1947. Most of these events are now known to be due to two types of particles: (i) Λ^0 , which decays into a proton and a negative π -meson: $\Lambda^0 \rightarrow P + \pi^-$, with a release of energy between 35 and 40 MeV.^{2,3}; and (ii), θ^0 , a heavy neutral meson which transforms into two light mesons, probably π -particles: $\theta^0 \rightarrow \pi^+ + \pi^-$, with an energy release of approximately 210 MeV.^{2,4}. The mean life-times of the two types are approximately $t_{\Lambda^0} \sim 3 \times 10^{-10}$ s., and $t_{\theta^0} \sim 2 \times 10^{-12}$ s., respectively⁵.

It is now known that the Λ^0 -particle can be produced in nuclear interactions in which the available kinetic energy is insufficient to provide all the rest-

* The nomenclature employed is that recently proposed by Amaldi *et al.* (*Nature*, 173, 123; 1954). A hyperon is a particle with mass between that of the neutron and that of the deuteron.

mass of the particle^{6,7}. It is therefore believed that it results from a modification of a nucleon as a result of the collision. This fact, and the observation that in its decay it is transformed into a proton, suggests that it may be useful to regard it as an 'excited' nucleon. An excited atom can return to its normal state of energy by emitting a quantum of radiation, a photon; by analogy, an excited nucleon is conceived to relax by emitting a 'heavy quantum' of the nuclear field, that is, a π -meson.

It has recently been found possible to make very accurate measurements of the mass of the Λ^0 -particle by the photographic method. In a stack of stripped emulsions, exposed at high altitude, Friedlander, Keefe, Menon and Merlin⁸ in Bristol have found eight examples of tracks due to the decay of Λ^0 -particles in each of which both the secondary proton and the negative π -meson are arrested in the stack. The ranges of the two particles can thus be measured, and thence their energies. These observations, and the angle of inclination with which the two particles are ejected, permit an accurate evaluation of the energy release, Q . The mean result thus obtained is 37.2 ± 0.5 MeV. in satisfactory agreement with the cloud-chamber observations. The corresponding value of the mass of the Λ^0 -particle is $2,182 \pm 2 m_p$. The quoted errors in the energy release are those deduced from the inner consistency of the measurements. The final value may have to be amended when a more accurate range-energy relation for protons has been established.

The original discovery suggesting that hyperons can exist not only as free particles but also bound within nuclei was due to Danyasz and Pniewski⁹. They observed a heavy nuclear fragment, of charge $\sim 5e$, emitted from a nuclear disintegration recorded in a photographic plate exposed to the cosmic radiation. The particle appeared to reach the end of its range, where it disintegrated with the emission of three or four charged particles.

The striking feature of the observation was that the disintegration occurred at the end of the range, when the parent particle was at rest, or moving with very low velocity. The secondary disintegration could not therefore be due to a collision of the fragment with another nucleus. Instead, it was attributed to the spontaneous disintegration of the fragment. This view, however, had to meet the following difficulty. When a nucleus is struck by a nuclear particle, such as a proton, large amounts of energy can be conveyed to it so that it becomes violently excited. We picture the nucleons as being put into a state of violent motion, a motion of 'thermal agitation', as a result of which the nucleus disintegrates, several of its nucleons being 'evaporated'. The time for such a process is believed to be of the order of 10^{-14} s. In the case of the fragment observed by Danyasz and Pniewski, however, its time of flight, from the instant of its ejection to the moment of arrest at the end of its trajectory, was $\sim 3 \times 10^{-12}$ s. The particle, therefore, survived at least several million times longer, before disintegrating, than would be expected according to our conventional picture of nuclear excitation.

In order to resolve this difficulty, Danyasz and Pniewski suggested that the observed effects were due to the presence, among the nucleons of the fragment, of a hyperon—an excited nucleon. The observed disintegration was then associated with the decay of the hyperon. Alternatively, they suggested that the fragment might have emerged from the

parent disintegration with a meson moving around it in a bound orbit. The disintegration of the fragment was then to be attributed to the capture of the meson, and the liberation, among the nucleons, of the energy corresponding to the rest-mass of the meson. Such disintegrations due to nuclear capture of free π -mesons arrested in photographic emulsions are commonly observed in plates exposed to cosmic radiation.

Very shortly after the first observation, a second similar example, involving an ejected nuclear fragment of charge 2 or 3, was found by Tidman *et al.*¹⁰. This observation was important because it appeared to eliminate the possibility, certainly very remote, that the original event was due to the chance occurrence, precisely at the end of the track of the nuclear fragment, of a small unrelated disintegration.

Some months later, two further similar events were discovered by Crusard and Morellet¹¹ and by Frauer¹², which appeared to exclude the possibility that the phenomenon was to be attributed to a π -meson in a bound orbit. In each of the new events, a small disintegration with three secondary charged particles occurred at the end of the range of an ejected nuclear fragment of small charge, and one of the secondary particles could be proved to be a π -meson. Such an observation cannot be interpreted in terms of the nuclear capture of a π -meson, as this would provide insufficient energy to account for the disintegration. This difficulty could be avoided if the captured meson were assumed to be of greater mass—a χ -meson, for example. In both the new events, however, the release of kinetic energy appeared to be of the order of 40 MeV., a value consistent with the original assumption of the presence of a Λ^0 -particle among the nucleons of the ejected fragment. Very strong evidence for the correctness of this view has now been provided by two further examples which, because of the simplicity of the nuclear systems involved, allow a very precise analysis.

In the example described by Hill *et al.*¹³, the ejected particle is probably a nucleus of mass number 4, charge 2. At the end of its range it appears to disintegrate into a π -meson and two other charged particles. If the transformation is represented:

there is a momentum balance among the secondary charged particles, and the release of energy is ~ 33.8 MeV. A detailed analysis, using the accurate value for m_{Λ^0} , shows that, if the above interpretation is correct, and if the original fragment contains a Λ^0 -particle within it, the binding energy of the latter is ~ 4 MeV. This value may be compared with the energy required to remove a neutron from an α -particle, namely, ~ 20 MeV.

An event recently described by Bonetti *et al.*¹⁴ allows an even more detailed analysis. The mass of the ejected fragment, of charge 6, can be determined, and the value found is $\sim 5,500 m_p$ —approximately the mass of the triton. At the end of its range, the particle disintegrates into two charged particles which recoil in opposite directions, so that the two tracks are collinear. One of the secondary particles is a π -meson of great range which, on stopping in the stack, is captured by a nucleus and disintegrates it. The other produces a short recoil track. If this particle is assumed to be a nucleus of helium-3, as appears to be demanded by the need to conserve

mass-number and charge, its momentum, as deduced from its range, is found to equal that of the π -meson. The transformation may therefore be written:

The total release of energy is 41.5 MeV., a value which corresponds to a binding energy of the Λ^0 -particle to the other two nucleons of the excited triton equal to about 1.5 MeV.

The latest two events, which allow such a close analysis, appear finally to exclude the possibility that the phenomenon under discussion is to be explained in terms of a meson in an orbit around the nucleus. Such an explanation, in the case of a light meson (π), has already been eliminated by the observed emission of π -mesons from the disintegrating fragment; but the possibility of a heavy meson remained. In the last two events, however, there is a momentum balance among the charged secondary particles, and the total release of kinetic energy is about 40 MeV. If the disintegrations are attributed to the nuclear capture of a negative heavy meson, an energy of ~ 300 MeV. remains unaccounted for. The emission of a neutral particle, or particles, of high energy and momentum, would therefore have to be assumed. The observed momentum balance, so convincingly demonstrated in the event described by Bonetti *et al.*—together with the values of the binding energy of the Λ^0 -particle deduced on the basis of the alternative assumption—would then have to be regarded as fortuitous. Such a possibility is remote and can be rejected on the grounds of its extreme improbability. It appears, therefore, that the explanation in terms of a Λ^0 -particle is alone acceptable.

In view of the many laboratories now working on the subject, it seems certain that many further examples permitting a detailed analysis will soon be found. In time, it should be possible to determine the binding energies of the Λ^0 -particle in a variety of nuclear species. It has been pointed out by Cheston and Primakoff¹² that a particularly interesting example, not hitherto observed, would be an excited deuteron:

It remains to be seen, however, whether the cohesion between a Λ^0 -particle and a single proton is strong enough to render such an assembly sufficiently stable to be observed.

It has been suggested in an earlier paragraph that it may be useful to describe the Λ^0 -particle as an excited nucleon, but it is already clear that the analogy is of limited validity. An excited hydrogen atom, to use the simplest example, consists of a proton and an electron in a state of higher energy than in the normal atom. The analogy might then suggest that the excited nucleon consists of a proton and an associated π -meson—that the Λ^0 is a composite particle. Such a view could not have been finally excluded while our knowledge was confined to the decay of the free Λ^0 -particles. Their relative stability as components of nuclei appears, however, to do so, for it is generally believed that, when captured by a nucleus, a π -meson interacts with its nucleons in a time short compared with 10^{-13} s., the disappearance of its rest-mass providing the energy of the disintegration. In the event described by Bonetti *et al.*, however, the nuclear fragment per-

sisted for longer than 2×10^{-10} s. before disintegrating. If the Λ^0 -particle consisted of a π -meson bound to a proton, it is difficult to see how the nuclear fragment could persist for such a long time on a nuclear time-scale. One would expect the bound π -meson to disintegrate the nucleus just as it does when captured from outside.

These considerations suggest that the Λ^0 -particle is an excited nucleon in a different sense from that suggested by familiar analogies. We are entering a new field where basically new concepts remain to be established; but it seems reasonable to conjecture that the nucleon is transformed into an excited nucleon as a result of changes in its internal constitution. If so, we are beginning to make a new penetration into what Maxwell called "the strange strata of the material world", a penetration into the world of the nucleon. It seems that matter is inexhaustible.

OBITUARIES

Mr. Albert Campbell

ALBERT CAMPBELL, who died in Cambridge on February 6 at the age of ninety-one, will long be remembered as a pioneer in electrical science, especially in the fields of alternating current measurements and standards. He was one of the small band of men who under Glazebrook's leadership built up the National Physical Laboratory from almost nothing in 1901 to the research laboratory with a world-wide reputation that it had already become when Glazebrook retired in 1919. Campbell himself retired a little before Glazebrook, though not for the same reason; he had not reached the customary retiring age, but he realized that conditions were changing. To be a leading member of a research team in a government laboratory was a very different prospect from being a pioneer opening up new ground with freedom to move in whatever direction the spirit prompted. He retired and continued to work at home with home-made instruments, until, with a failing memory, he found himself no longer able to do scientific work.

The main body of Campbell's work was, of course, done at the National Physical Laboratory between 1901 and 1919, the most important single item being his primary standard of mutual inductance, constructed in 1907 and still the ultimate reference standard for nearly all the measurements of inductance, capacitance and related quantities made in

Great Britain. The work he did after his official retirement was, however, no less remarkable. It included his alternating-current potentiometer, which in some respects has not been surpassed, and also his best method for the absolute determination of the ohm. Has any other man three absolute methods to his credit? Naturally enough, with home-made instruments his accuracy was limited to barely 1 part in 10,000, but when elaborated at the National Physical Laboratory his method proved to rank with the best known to-day.

It is scarcely possible to indicate the scope of his work in a short note, but it is worth recalling that he devised the inductometer (his name for a continuously adjustable and direct-reading standard of inductance), the constant-inductance rheostat, the vibration galvanometer, the 'waveform sifter', one of the earliest electrical filters and the forerunner of the modern twin-T bridges. He set up the first standard wavemeter at the National Physical Laboratory, calibrated it absolutely by counting flashes in an oscillatory arc, and showed that the result agreed with values calculated from his measurements of inductance and capacitance. He also devised many alternating current bridges and methods for measuring all the magnetic properties of importance to the electrical industry.

Campbell's strong practical bent is the more remarkable in that at Cambridge he first read for the Mathematical Tripos, from which he went on to the natural sciences. In 1893 Alexander Russell persuaded him to go to Faraday House, London, where he remained until he joined Glazebrook. It was no doubt there that he acquired his insight into the scientific needs of the rapidly growing electrical industry, which he served so well in his own inimitable way later.

It is remarkable that, with one notable exception, none of the scientific honours that it is customary to shower on a man of his distinction seems to have come his way. He was a man of singular personal charm who showed the same interest in all his fellow-workers from the boy in the workshop to the clerk in the office and the most eminent scientific man of his time. One of these last once remarked of him that "Nobody had a kinder heart or a sharper tongue", from which it may be inferred that he was sometimes a thorn in the flesh of the authorities. In 1925 the Physical Society awarded him the Duddell Medal; and never was that honour more appropriately bestowed or more richly deserved.

L. HARTSHORN

Prof. D. S. Belyankin

WITH the death of Dmitry Stepanovich Belyankin, the U.S.S.R. has lost one of their most prominent petrologists. He was born on August 28, 1876, in Lomanikha, Vologda district, and died on June 20, 1953, in Moscow. Trained as a chemist under G. Tammann in the University of Yuriev (Dorpat), he occupied successfully the posts of lecturer and of professor of mineralogy and petrology in the St. Petersburg Polytechnic Institute.

After his election as corresponding member of the Academy of Sciences in 1938, he became a member of the Petrographical Institute of the Academy, and moved to Moscow in 1935. In 1943 he was elected a full member of the Academy and after that he occupied a number of its more important posts, being

director of the Petrographical Institute and the Mineralogical Museum, editor of the Geological Section of the Bulletin and co-editor of the *Compte Rendu (Doklady)* of the Academy.

Belyankin published some three hundred and eighty papers and books (many of them written in collaboration), dealing with mineralogy, regional and descriptive petrology and technical petrology. He was particularly interested in feldspars, clay minerals and other silicates, and described and named several new species. He described various igneous rocks from Northern Russia, the Ural Mountains and the Caucasus, and wrote papers on magmatic differentiation and the nomenclature of igneous rocks. He was particularly interested in the development of technical petrology, of which he was the acknowledged master. He created the Russian school in this subject and he and his collaborators contributed a large number of works dealing with the study of refractories, ceramic products, glasses and metallurgical slags.

Belyankin combined an all-absorbing devotion to science with a friendly disposition towards all his pupils and friends, among whom I was proud to be included.

S. I. TOMCHIKOFF

Prof. Giorgio Valle

ITALIAN science has suffered a grievous loss by the sudden death last December of G. Valle, head of the Department of Physics and director of the Righi Institute of the University of Bologna. Valle, who was born on December 15, 1888, at Trieste, read physics at the University of Vienna, where, having taken the degree of Dr. Phil., he worked as a demonstrator under E. Lecher until 1914. After the First World War, Valle taught for a short time at the Technical School at Terni and was later appointed professor at the Technical Institute at Bologna. In 1922 he moved to Asti, where he taught science at the Classical High School, at the same time lecturing to advanced students at the University of Turin. In 1932 he was appointed professor of experimental physics at the University of Ferrara, and in 1938 to the chair of physics at Parma, which he held until 1947. In that year he was elected to the chair of physics at Bologna, a post formerly held by A. Righi and Q. Majorana.

Valle, an assiduous worker, published more than seventy papers, mostly in *Nuovo Cimento*, the proceedings of the Accademia dei Lincei and of the Accademia di Torino, the *Wiener Berichte* and the *Physikalische Zeitschrift*. He made a series of notable contributions in the field of electric discharges, also in magnetism, acoustics, physical optics and meteorology. He was author or co-author of several text-books as well as of a volume of extracts from Righi's papers (see *Nature*, 167, 174; 1951) which he published in collaboration with G. C. Dalla Nave.

Valle was a man of great energy and vitality, and although during the past few years handicapped by the loss of his voice, he continued his scientific work until a month before his death. At the Righi Centenary Celebrations at Bologna in 1950, Valle, as an officer of the Italian Physical Society, was host to scientists from many countries, including Great Britain. A few months before his death he was at last able to gratify his wish to visit England, where he took part in the Oxford conference on ionization phenomena.

A. VON ENGEL

NEWS and VIEWS

Scientific Adviser's Branch, Home Office :

Sir Edward Paris, C.B.

SIR EDWARD PARIS, who has recently retired from the position of chief scientific adviser to the Home Office, received his early scientific training at the Imperial College of Science and Technology and at University College, London, where he worked with Prof. A. W. Porter on the polarization of light. During the First World War he saw service in a Sound-Ranging Section in France. He there came into contact with Major W. S. Tucker, and, after the War, Tucker and Paris collaborated first at the Munitions Inventions Department and afterwards at the Signals Experimental Establishment, Woolwich, in their investigation of the use of the hot-wire microphone for sound detection. Between the two Wars, Paris worked as an experimental officer in the Air Defence Experimental Establishment until, in 1938, he was appointed deputy director of scientific research at the War Office under Dr. H. J. Gough. A year later the scientific branches were transferred to the Ministry of Supply, and it was there, under the stress of war, that Paris showed great qualities as a scientific administrator. Like others in senior posts in that Ministry at the time, he went through a bewildering succession of changes of designation, denoted by ever more complicated initials; but he remained unperturbed and unperturbable, and the work went on. In 1946 he was principal director of scientific research (defence). He was created C.B. in 1947. In 1948 he was appointed to the Home Office, and there, as chief scientific adviser, he has been conspicuously successful in directing the research and advising on the scientific problems arising in the civil defence planning in Britain for which the Department is responsible. The conferment of a knighthood on him, announced in the New Year Honours, has given great pleasure to his friends and colleagues.

Dr. R. H. Purcell

DR. R. H. PURCELL, who has been appointed to the post of scientific adviser to the Home Office in succession to Sir Edward Paris, took a degree in chemistry at the Royal College of Science in 1924. After conducting research under Prof. H. B. Baker, he was elected to a Ramsay Memorial Fellowship which he held at Amsterdam and the Royal College of Science. He later became lecturer in physical chemistry in the Royal College of Science. He joined the scientific staff of the Admiralty during the War, and was occupied on a number of scientific inquiries which were of urgent practical importance. In 1947 Dr. Purcell was promoted to the rank of senior principal scientific officer for special scientific merit, and has only recently been made a deputy chief scientific officer in the Royal Naval Scientific Service. Since the War Dr. Purcell has been directly concerned with the naval aspects of defence against atomic weapons, and these experiences will be important to him in his new duties.

Canning Section of the Low Temperature Research Station, Cambridge :

Mr. T. N. Morris

MR. THOMAS NORMAN MORRIS, who retired at the beginning of this year from his post as head of the Canning Section of the Low Temperature Research Station, Cambridge, was born in 1889 at Haddenham,

Isle of Ely (Cambs), of local farming stock on both sides, and was educated in Cambridge at the County School for Boys and then at the University, being a scholar of St. John's College. After Part 1 of the Natural Sciences Tripos, in which his subjects were botany, chemistry, zoology and physiology, he read for the Agricultural Diploma and then in 1911 took botany in Part 2 of the Tripos. During the First World War he was bacteriologist for acetone production in H.M. Factory at King's Lynn and was later employed by the Ministry of Munitions on the production of picric acid as chemist in charge of the laboratory at Halifax, Yorks. After the War he was research chemist with the firm of Chivers and Sons, Ltd., Histon, Cambs, until in 1927 Sir William Hardy appointed him to be head of the Canning Section of the Low Temperature Research Station. Work in this Section was initially concerned with corrosion problems relating to tin-plate cans, but was later extended to include the freezing of fruits and vegetables, the concentration of fruit juices, the dehydration of foods and the behaviour of pectin in fruits during storage and processing, particularly in relation to the manufacture of jams and jellies. Apart from his scientific occupations, Mr. Morris's main interest is practical farming, and now that he has retired he intends to apply his scientific and agricultural knowledge to this end.

Prof. Otto Hahn

To mark the anniversary of his seventy-fifth birthday on March 8, Prof. Otto Hahn, the nuclear physicist, was awarded the Grand Cross, Second Class, of the Order of Merit of the Western German Federal Republic. He was invested with the insignia of the Order at the offices of the Max Planck Society, of which he is president; and on the same occasion he was awarded the Harnack Medal of the Society.

Napier Shaw Memorial Prize of the Royal Meteorological Society

MARCH 4 marked the centenary of the birth of Sir Napier Shaw, whose life extended into its tenth decade, spanning an era of scientific as of political revolution. Sir Napier's remarkable career can be divided into three main phases. As Fellow and senior tutor of Emmanuel College, Cambridge, he established a reputation as a successful university teacher of physics, an occupation which he abandoned only at the turn of the century to become director of the Meteorological Office, and president of the International Meteorological Organization, in which capacities he probably did more than any other man of his time to promote the subject by encouraging new observational methods, a scientific treatment of data, and meteorological research generally. Finally, at the age of sixty-six, he became the first professor of meteorology at the Imperial College of Science and Technology, London, and there laid the foundation of formal training in the subject.

As a result of an appeal to the members of the Royal Meteorological Society and to scientific instrument manufacturers, a memorial fund has been raised by the Society to commemorate the unique position which Shaw achieved in British meteorology. It has been decided to use this fund for the regular award by competition of a Napier Shaw Memorial Prize. The competition will be open to anyone without restriction of nationality. The prize of £100 is offered on this occasion for an original essay on "The Energetics of the General Circulation". The

essay will be expected to treat of the energy transformations of the circulation as a general theme or any particular aspects of that theme. It may be an essay in which the author describes and discusses the salient and essential features of the general circulation and the energy transformations involved; it may be an essay which attempts an adequate synopsis and discussion of the observations, or a study of the thermodynamics and hydrodynamics of the circulation; or the essay may treat of any combination of these within the general theme. The essay, which must be in English, may include material which the candidate has already published. Essays may be submitted jointly in the names of more than one author. All entries must be addressed to the Assistant Secretary, Royal Meteorological Society, 49 Cromwell Road, London, S.W.7, and marked clearly 'Napier Shaw Prize', and should be received at the Society's Offices not later than March 4, 1956.

Royal Society of Edinburgh: New Fellows

THE following have been elected Fellows of the Royal Society of Edinburgh: Dr. H. M. Adam, senior lecturer in pharmacology, University of Edinburgh; Mr. J. K. Allan, chief geologist, National Coal Board, London; Mr. B. L. Burt, principal scientific officer, Royal Botanic Garden, Edinburgh; Dr. Enid Charles, reader in demography and vital statistics, University of Birmingham; Dr. E. F. Collingwood, Lilburn Tower, Northumberland; Dr. I. MacP. Dawson, senior lecturer in electron microscopy, University of Glasgow; Dr. J. Duckworth, Rowett Research Institute, Bucksburn; Mr. W. G. Emmett, reader in experimental education, University of Edinburgh; Dr. C. E. Foister, chief plant pathologist, Department of Agriculture for Scotland; Mr. H. D. Griffith, lecturer in natural philosophy (medical physics), University of Aberdeen; Prof. G. Hibberd, Dixon professor of mining, University of Glasgow; Prof. N. Kemmer, Tait professor of natural philosophy, University of Edinburgh; Mr. T. Lawrie, general manager, North of Scotland Hydro-Electric Board; Prof. R. D. Lockhart, professor of anatomy, University of Aberdeen; Dr. C. Long, senior lecturer, Department of Biological Chemistry, University of Aberdeen; Dr. D. K. O. MacDonald, director, Cryogenic Laboratory, Division of Physics, National Research Council, Canada; Miss Agnes E. Miller, lecturer in zoology, University of Glasgow; Prof. D. C. Mack, professor of mathematics, Royal Technical College, Glasgow; Dr. Mary Pickford, reader in physiology, University of Edinburgh; Dr. B. Raistrick, research manager, Scottish Agricultural Industries, Ltd.; Prof. G. S. Rushbrooke, professor of theoretical physics, King's College (University of Durham), Newcastle upon Tyne; Mr. G. I. Scott, consultant ophthalmologist, Edinburgh; Dr. N. B. Slater, lecturer in applied mathematics, University of Leeds; Dr. R. B. Strathdee, reader in chemistry, University of Aberdeen; Mr. J. Wallace, head of the Science Department, Melville College, Edinburgh.

Research Into Rain-making

REPLYING in an adjournment debate in the House of Commons on February 23 to Mr. G. de Freitas's request for increased research into weather modification, the Under-Secretary of State for Air said that the Meteorological Office is studying reports of rain-making activities all over the world; but he was advised that available scientific evidence on the

practical side is not entirely convincing. Since the Advisory Council on Scientific Policy expressed the opinion in 1951 that no expenditure of effort on large-scale field trials was called for without further research, the Meteorological Office has carried out research on cloud rainfall problems, and practical experiments have been made by the Meteorological Research Flight of the Royal Air Force, more with the object of increasing knowledge than of trying to produce rain. Rain-making, and the present state of our knowledge of the subject, will shortly come before the Physical Sub-Committee of the Meteorological Research Committee, which advises the Secretary of State for Air on this subject, and the future course of action will then be reconsidered.

National Institute of Sciences of India: Council and New Fellows

THE Council of the National Institute of Sciences of India has been elected for 1954 as follows: *President*, Sir K. S. Krishnan; *Vice-Presidents*, Prof. S. K. Banerji and Dr. B. Mukerji; *Treasurer*, Prof. D. S. Kothari; *Foreign Secretary*, Prof. P. C. Mahalanobis; *Secretaries*, Prof. R. C. Majumdar and Dr. B. P. Pal; *Editor of Publications*, Prof. J. M. Sen; *Members of Council*, Prof. S. P. Agharkar, Prof. K. N. Bagchi, Dr. J. L. Bhaduri, Dr. Verrier Elwin, Prof. P. S. Gill, Prof. A. C. Joshi, Dr. V. R. Khanolkar, Dr. M. S. Krishnan, Dr. D. R. Malhotra, Prof. S. K. Mitra, Dr. M. A. Moghe, Dr. H. S. Pruthi, Prof. B. Sanjiva Rao, Dr. V. Subrahmanyam, Prof. N. R. Tawde, Mr. M. S. Thacker and Dr. A. O. Ukil; *Representative of the Government of India*, Dr. D. N. Wadia; *Representatives of the Asiatic Society*, Prof. H. K. Mookerjee and Dr. U. P. Basu; *Representatives of the National Academy of Sciences*, Prof. Shri Ranjan and Dr. R. K. Saksena; *Representatives of the Indian Science Congress Association*, Dr. S. L. Hora and Dr. B. N. Prasad; *Ex-Officio Members (Past Presidents)*, Dr. Baim Prashad, Dr. J. O. Ghosh, Dr. D. N. Wadia, Sir S. S. Bhatnagar, Prof. S. N. Bose and Dr. S. L. Hora.

The following elections have also been made to fellowships of the Institute. *Honorary Fellows*: Prof. Sydney Chapman, recently Sedleian professor of natural philosophy, University of Oxford; Prof. V. A. Engelhardt, Soviet Academy of Sciences, Moscow; Prof. W. Heisenberg, director of the Max Planck Institute, Göttingen; and Prof. Paul Karrer, director of the Chemistry Institute, University of Zurich. *Ordinary Fellows*: Dr. B. C. Basu, research officer in entomology, Indian Veterinary Research Institute, Izatnagar; Dr. S. K. Bhattacharya, assistant professor of chemistry, Institute of Technology, Kharagpur; Prof. K. Chandrasekharan, professor of mathematics, Tata Institute of Fundamental Research, Bombay; Prof. K. R. Dixit, professor of physics, Institute of Science, Bombay; Dr. S. Ghosh, professor of chemistry, University of Allahabad; Dr. A. G. Jhingran, superintending geologist, Geological Survey of India, Calcutta; Prof. S. Kilpady, professor of geology, University of Nagpur; Dr. Z. R. Kothavala, director, Dairy Research, Government of India, Bangalore; Dr. L. S. S. Kumar, principal, College of Agriculture, Pona; Dr. N. V. Modak, special engineer, Bombay Municipality; Prof. C. Radhakrishna Rao, professor, Indian Statistical Institute, Calcutta; Mr. A. K. Roy, officiating deputy director-general of observatories, Meteorological Office, New Delhi; Dr. R. N. Sen, lecturer in mathematics, University of Calcutta;

Mr. M. R. Sen Gupta, principal of the Engineering College, Banaras Hindu University; and Dr. S. M. Sircar, lecturer in botany, University of Calcutta.

Vitaminization of Margarine

ALTHOUGH skim milk has a high nutritional value, it is not a popular article of diet and, consequently, the separation of milk fat for use as cream or butter results in a considerable wastage of the valuable proteins, minerals and water-soluble vitamins. There can be little doubt that nutritional economy demands the use of milk as whole milk, not separated into different fractions. In communities where butter has become a regular item in the diet, it then becomes necessary to find a butter substitute, chiefly as a 'spreader' for bread. Almost any hardened edible oil would do for this purpose; but in order to safeguard the health of those who will not take enough milk to yield the amount of milk fat they would otherwise have taken as butter, it is important that butter substitutes should be reinforced with the fat-soluble vitamins A and D to approximately the same levels as are normally found in butter. A high proportion of margarine of domestic quality in Britain was already being reinforced in this way in 1939; but it was only during the War that it became a statutory condition of licence to manufacture that these two vitamins should be added in prescribed quantities. Now that margarine is due shortly to be decontrolled, the Food Standards Committee of the Ministry of Food has recommended that all home-produced and imported domestic margarine should be required to reach the following levels: vitamin A, 760-940 international units/oz.; and vitamin D, 80-100 international units/oz. The recommended level for vitamin D is approximately the same as that at present prevailing; that for vitamin A is somewhat higher, the present level being 450-550 international units/oz. The report has been issued by the Ministry of Food.

Limits for Zinc in Foods

ALTHOUGH zinc is a normal constituent of the human body and its presence in the enzyme carbonic anhydrase suggests that it may be an essential element in the diet, nevertheless far more importance is attached to the necessity of avoiding an excessive intake than of ensuring an adequate one. The Food Standards Committee (Metallic Contamination Subcommittee) of the Ministry of Food in a report, in a recent publication issued by the Ministry, recommends that the following limits should be observed: beverages which are ready to drink, 5 p.p.m.; and other foods, 50 p.p.m. But it adds that "in view of the high natural zinc content of certain animal and vegetable products, e.g. herrings, shell-fish, and crustacea, cereal offals and animal offals . . . no objection should be taken to the sale of such articles containing zinc in excess of 50 p.p.m. if it can be shown that the zinc is of natural occurrence". A maximum limit of 100 p.p.m. is already prescribed for edible gelatin and, apart from this, the Committee does not consider it necessary that statutory effect need be given to the limits recommended. It would appear that risk of zinc poisoning comes almost entirely from the use of zinc or galvanized iron equipment in kitchens and food stores. Such equipment is corroded not only by acid foods (for example, apples) but also by salt solutions, so that it is generally unsuitable for any cooking or food-storage purposes. The Committee also directs

attention to the fact that "outbreaks of poisoning have been attributed to the inadvertent use of galvanized vessels, for example, to drinking rain water collected from galvanized iron roofs or stored in galvanized iron tanks". The main symptom of zinc poisoning is an outbreak of violent vomiting.

The Earth's Shadow

AN article in *l'Astronomie* (November 1953), entitled "Sur l'Ombre de la Terre", by J. Dubois, of the Bordeaux Observatory, gives the results of some recent research, and more especially of his own work carried out at the Pic-du-Midi Observatory and at Bordeaux, on the phenomenon of the earth's shadow or the anticrepuscular arch. This phenomenon, which occurs a short time before sunrise and a short time after sunset, is briefly described for sunset; but the same description in inverse chronological order applies also at sunrise. As soon as the apparent altitude of the sun is less than about 2° , a greyish-blue zone rises above the eastern horizon, slowly ascending as the sun sinks, changing in colour from blue to an increasing dark hue, and ending as a vast surbased arc, forming what is known as "the earth's shadow". Some minutes after sunset a whitish zone, somewhat bright, called "Albe" by M. Durand-Greville, is clearly distinguished, and to it is due the re-illumination of clouds or of the tops of mountains—phenomena which have puzzled many observers and for which various theories have been proposed. In a discussion of the history of the observations and aim of the researches, reference is made by M. Dubois to the observations of Gruner and R. P. Combiar, the latter having published the results of his work during the years 1938-40. However, it is to M. Dubois that the most important work is due, and all who are interested in the phenomenon would be well advised to read the description of his equipment and his conclusions. In this short note, attention can merely be directed to a few of his deductions, from the time when he started work in 1945 until he completed it four years later. He points out that the conclusions deduced by observations with the spectrophotometer are consistent with his theories, and that the main factor in promoting the anticrepuscular arch is the ozone in the atmosphere localized between heights of 20 and 30 km. The blue tint observed must be attributed to the feeble intensity of the yellow and red radiations which are rather strongly absorbed by the ozone. It appears that absorption by aqueous vapour and oxygen has very little effect on the intensity and colour of the arch.

Blundell's School Science Society

THE recent edition of the *Magazine of the Blundell's School Science Society* (No. 8, 1952-53) reveals a year of considerable activity which continues to reflect exceptional credit on the School's activities, especially in biological field work. This practical work carried out by the boys is obviously well organized, for the papers published show the real research spirit. The School has now started a colony of bees, and a tank of sticklebacks is being kept not merely for amusement but also for behaviour studies. These practical activities are supplemented by periodic demonstrations and Sunday evening talks by visiting scientists. The opening meeting of the year was addressed by Mr. A. Stuart, head of the Geology Department, University College, Exeter. Then throughout the year, lectures on varying scientific topics were given.

The *Magazine* reports "Meteorological Records", by D. S. R. Wills, which is a summary of the local weather during October 1952–September 1953. In the bird-ringing work, 164 birds were ringed—125 from traps and 39 from nests. The Ornithological Section also gives a detailed analysis of nest record cards for 1953 (J. Beek), and an account of the birds of the Culmstock area. A paper entitled "A Study of the Influence of Light and Soil Properties on the Growth of Bracken" presents results of an excellent piece of field and experimental work by D. P. T. Burke. The realization that biology is the study of plants and animals living together in a community (rather than the uninspiring study of type specimens from books or, at most, dead bodies and pickle jars) comes out well in C. N. A. Clement's paper on "The Part Played by the Oak Tree in the Natural Plant and Animal Community of a Woodland". D. Knight Jones records some good experimental studies in his "Investigation of the Post-Floral Movements shown by the Garden Nasturtium". C. L. Honeybourne reports some "Observations on the Circulation of Nitrogen in the Grand Western Canal"; the field work here was carefully planned and carried out, and the observations include estimation of nitrogen in the water and of plankton. This excellent paper is accompanied by a table and two graphs. In the Spring Term of 1952, J. M. Saxon began some interesting observations on soil temperatures under natural conditions, using a thermistor.

Blundell's *Magazine* is a model of its kind and reflects great credit on the methods of science teaching in that School, for which Dr. M. Ashby, the biology master, is to be specially selected for congratulation.

Fungi Pathogenic to Man and Animals

A COLLABORATION of fungi is maintained in the Laboratory of Mycology of the Instituto Oswaldo Cruz (Caixa Postal 926, Rio de Janeiro, Brazil: List of Cultures, 1953). The workers in this laboratory are specially interested in the maintenance of cultures of fungi pathogenic to man and animals, though the list, which is a considerable one, contains many others, including plant pathogens. Scientists and institutions are asked to send cultures not included in the list. Cultures from the Institute's collection will be sent "to all institutions and scientists upon request and free of any charge".

A New Modelling Medium

A NEW modelling medium called 'Vinagel' is described in the November issue of the *Museums Journal* by Dr. H. F. Steedman, of the Zoology Department, University of Glasgow. At present it can be obtained in four grades, Nos. 116, 118, 500 and 577, from Vinyl Products, Ltd., Butter Hill, Carshalton, Surrey. To use the No. 116 grade it is sufficient to press it on a coin or other hard material, peel it away gently and bake in an oven for about twenty minutes at 170° C. On cooling, it will have the consistency of stiff rubber, will be highly resistant to deformation and virtually insoluble. With the softer varieties the material may be painted or dabbed with the 'Vinagel' until a sufficient thickness is obtained, and then the original and its covering must be baked as before. Its great optical resemblance when cured to bone suggests that one of its most important biological uses lies in osteology, though it will be certain to be of service to sculptors, artists and museum technicians.

Announcements

We regret to announce the following deaths:

Mr. S. F. Ashby, formerly director of the Imperial Mycological Institute, on March 6, aged seventy-nine.

Prof. E. P. Cathcart, C.B.E., F.R.S., emeritus professor of physiology in the University of Glasgow, on February 18.

Prof. J. L. Coolidge, emeritus professor of mathematics in Harvard University, aged eighty.

Prof. O. Diels, emeritus professor of chemistry in the University of Kiel, on March 7, aged seventy-eight.

Dr. N. G. Horner, formerly editor of the *British Medical Journal*, on March 7, aged seventy-two.

OWING to the increasing activities of the Society of Dyers and Colourists (19 Piccadilly, Bradford 1), the post of editor and general secretary of the Society, held by Dr. C. J. W. Hooper, has been divided, with Dr. Hooper continuing as editor and technical officer. The new post of secretary of the Society is being filled by Mr. J. W. Nicholls, who until recently has been working in Newcastle upon Tyne as secretary and organizer of the Federation of Master Builders.

CHANGES in the chairmanship in research boards of the Department of Scientific and Industrial Research have been announced as follows: *Building Research Board*, Sir Herbert Manzoni, city engineer of Birmingham, in succession to Mr. W. K. Wallace, chairman since 1949; *Food Investigation Board*, Dr. R. Holroyd, director of research, Imperial Chemical Industries, Ltd., in succession to Sir Frank Engledow, chairman since 1947; *Geological Survey Board*, Sir Walter Drummond, deputy chairman of the National Coal Board, in succession to Sir Arthur Trueman, chairman since 1943, who has retired from the post owing to ill-health; *Road Research Board*, Mr. E. J. Powell, county surveyor of Glamorgan, in succession to Sir Frank Smith, chairman since 1946.

THE United Steel Companies, Ltd., have recently endowed a fellowship for research in ferrous metallurgy at the University of Sheffield, and Dr. A. R. Entwistle, who for some time past has been engaged in metallurgical research in Sheffield, has been appointed as the first holder. Dr. Entwistle will study the effect of interstitial elements on the formation of martensite.

As in former years, a course in tropical hygiene for laymen will be held by the Ross Institute of Tropical Hygiene, London, during July 26–30. The course is for workers in the tropics holding posts which entail looking after the health and welfare of others. Morning sessions will be devoted to malaria and its control, and in the afternoons other tropical diseases and problems, such as hookworm, bilharzia, nutrition, housing and sanitation, and protection against heat will be dealt with. There is no fee for the course. Further information can be obtained from the organizing secretary, L. G. Ponsford, Ross Institute of Tropical Hygiene, London School of Hygiene and Tropical Medicine, Keppel Street (Gower Street), London, W.C.1.

ERRATUM. In the communication entitled "Possible Existence of a Transition Point between β - and γ -Sulphur", by R. S. Bradley, Dr. N. H. Hartshorne and M. Thackray (*Nature*, February 27, p. 400), the legend on the ordinate of the graph should read "Log-rate (mm./hr.)".

ATOMIC WEAPONS*

IN ordinary explosives, energy is released at high speed as a result of the rearrangement of unstable molecules into more stable forms. Since the energy is of the same order of magnitude for all chemical reactions, chemical explosives much more powerful than those available at present will never be found. In atomic weapons, however, energy is generated by the rearrangement of particles in the atomic nuclei. Nuclei are always lighter than their constituent particles, and this mass defect is a measure of the energy that would be liberated if the nucleus could be built up from its components. Since the mass defect is greatest for elements of medium atomic weight, there are two possible sources of atomic energy, namely, the building up of nuclei of medium elements from lighter ones and the breaking down of heavy elements to medium ones. The latter is the fission process on which the atom bomb is based.

To produce an explosion, the release of energy must be practically instantaneous. The fission of uranium-235 or plutonium-239 can be made to fulfil this requirement if a chain reaction is set up propagated by fast neutrons. At each fission, two or three fast neutrons are liberated, and if the mass of the fissionable material is great enough to ensure that more than one of these neutrons produces further fission, a chain reaction is initiated which runs its course in a few millionths of a second, producing a shock wave of unprecedented destructive force.

In January 1950, the President of the United States announced that he had directed the continuation of work on all forms of weapons "including the so-called hydrogen bomb". This made public the possibility of producing energy by the fusion of light

* Summary of a lecture by Prof. O. R. Frisch, O.B.E., F.R.S., being the second of the series of public lectures arranged by the Atomic Scientists' Association and the Department of Extra-Mural Studies of the University of London (see *Nature*, February 27, p. 336).

elements into heavy ones. In January 1953 it was announced that a thermonuclear test had taken place at Eniwetok, and in August 1953 Malenkov stated that "the U.S. no longer has the monopoly of the hydrogen bomb".

Little is known publicly about the construction of the hydrogen bomb; but most probably it is based on the fusion of hydrogen nuclei into helium nuclei, taking place at very high temperatures. The temperatures necessary for such reaction are of the order of millions of degrees and can only be produced by a fission bomb; the hydrogen bomb must thus be triggered by a fission bomb. It is fairly certain that hydrogen is the main material for a thermonuclear bomb, for the fusion of heavier elements requires much higher temperatures and produces less energy; but ordinary hydrogen is not suitable, and either deuterium or tritium have to be used.

The main advantage of the hydrogen bomb is that there is no essential limit to its size. It is a very safe explosive, for it will never go off unless fired by the fission bomb. The latter, on the other hand, is by nature unsafe and goes off the instant it is assembled, which puts a practical limit to its size. The load capacity of modern aircraft would, however, limit the explosive power of the hydrogen bomb to about a thousand times that of the fission bomb. The radius of damage of such explosive would thus be ten times greater than that of a fission bomb, that is, about ten miles for severe damage.

Against the background of Nature, atomic weapons are small. An average local thunderstorm releases as much energy as a plutonium bomb; a hurricane or an earthquake, a million times as much. Nevertheless, they are frightful weapons, capable of inflicting terrible destruction and wholesale death.

MANAGEMENT OF PUBLIC CORPORATIONS

THE Select Committee appointed in December 1951 "to consider the present methods by which the House of Commons is informed of the affairs of the Nationalized Industries and to report what changes, having regard to the provisions laid down by Parliament in the relevant statutes, may be desirable in these methods" issued last year a second report* which indicates very clearly how far we yet are from a satisfactory solution to the problem of parliamentary accountability. The Committee's first report was confined to the Parliamentary 'question' and stressed the limitations of this method of keeping Parliament informed and securing public accountability, rather than offering a fresh contribution towards the solution of what is increasingly recognized as a problem of national importance. In this first report, it was apparent from the evidence submitted to the Committee that, while the import-

ance of the public issues involved is widely appreciated, there is also a considerable difference of opinion as to the means for improving the present unsatisfactory situation, and also some misunderstanding as to the possibility of reconciling in a practicable way the independence and flexibility which are essential if a public corporation is to be characterized by initiative and enterprise, with complete answerability to Parliament.

This is also characteristic of the Select Committee's second report. The clash of opinion is no less marked, and the Committee's recommendations are obviously contrary to the opinions, strongly held and sometimes vehemently expressed, of important witnesses. The value of the report may well lie in the material for critical examination and further constructive thinking which it affords in its minutes of evidence, rather than in its somewhat tentative recommendations. The most encouraging feature of the report is, in fact, the indication it supplies of a disposition to examine the whole problem objectively and to keep

* Report from the Select Committee on Nationalized Industries, together with the Proceedings of the Committee, Minutes of Evidence and an Appendix. Pp. xviii+118. (London: H.M. Stationery Office, 1953.) 4s. net.

criticism of the nationalized industries of Great Britain as free as possible from party politics.

To the reality of the general desire for more information about the nationalized industries the report freely testifies: this is essential for informed and constructive criticism. The Select Committee was equally concerned that the nationalized industries had insufficient opportunity of presenting their case to Parliament and the public, and were exposed to public pressure in various ways and to much irresponsible criticism. Lord Hurecombe, as well as Mr. Hugh Molson, parliamentary secretary to the Ministry of Works, gave evidence on this point; such arguments, and the need for accountability arising from the vast amount of capital and of income and expenditure involved in concerns which are under public ownership, and the direct impact of their charges upon everyday civilized life, quite apart from the Treasury guarantee of interest paid on their stock, led the Committee to consider the appointment of a Standing Committee of the House of Commons or of both Houses of Parliament to examine the nationalized industries and keep Parliament informed upon them.

The arguments for such a committee were advanced by Mr. Molson in his evidence, on the assumption that it would be concerned with elucidating fundamental problems of policy. Mr. Molson was evidently also of the opinion that such a committee would afford Parliament the means, from time to time, of taking stock of the situation, in much the way that Mr. Herbert Morrison had urged in 1950 in suggesting a periodic committee of inquiry at about seven-yearly intervals for each public corporation. Lord Hurecombe, who also supported the suggestion, thought that apart from helping to meet the legitimate demand of Parliament for further knowledge, the continuity of personnel on such a committee could contribute not merely to informed debate, but also to objective debate and to the removal of a controversial atmosphere so that constructive suggestions could be more readily made and received.

Strong representations were made in evidence to the Select Committee that the establishment of a permanent committee of inquiry into the nationalized industries would be both contrary to the spirit and intentions of the acts under which the industries were nationalized and also an innovation in, and hostile to, the general pattern of the British constitution. Lord Reith suggested that the appointment of such an *ad hoc* select committee was in effect a negation of Parliament's deliberate renunciation of the right of direct interference when it passed the nationalization acts. He regarded it as tantamount to institutionalizing the Parliament question and likely to lead to a direct collision between the industries and Parliament.

Although Lord Reith was strongly of the opinion that if any committee were set up it should be a committee of both Houses, that would not avoid the difficulties to which Lord Reith directed attention. Moreover, the committee must be an official committee: an unofficial committee is impracticable, because the contacts between the chairmen of the public corporations and Parliament must be upon an official basis. Lord Reith's own view was that a Royal Commission with wide terms of reference would be a much more effective means of achieving the desired purpose, and he elaborated the argument he advanced before the Public Accounts Committee

three years ago as well as earlier. Failing this, he suggested that there might be some minister responsible for the public corporations and provided with a small staff for the purpose, in much the same way as the Lord President of the Council is responsible for the work of the Medical Research Council, the Advisory Council for Scientific and Industrial Research and other bodies.

Lord Reith did not recommend the appointment of such a minister. He merely indicated that it was one way of dealing with the problem, and it was quite clear that such a proposal would still have to solve the difficulty of the parliamentary 'question' if control over day-to-day management is not to develop. He was obviously impressed with the possibility of a Royal Commission reaching a more satisfactory solution and providing constructive proposals on the basis of much more careful study and far-reaching objective inquiry than the complex and important issues involved had as yet received. The Select Committee was obviously impressed with Lord Reith's view and particularly the possibility it offered for more searching inquiry by fresh minds, not limited necessarily to Parliament itself. Nevertheless, in spite of similar arguments advanced by Mr. Herbert Morrison, its own recommendation was for the appointment of a Standing Committee and one of the House of Commons only.

Mr. Morrison did not specify a Royal Commission, but equally had in mind the advantage of a commission which was not limited to members of Parliament and which would be periodic rather than permanent. He emphasized that the responsibility for efficiency should lie on the industries themselves, and suggested that co-operation among the national boards might lead to the establishment of a common efficiency unit which would avoid the dangers inherent in one established for a particular corporation. Moreover, Mr. Morrison raised an objection to the proposed Standing Committee which went deeper and obviously impressed the Select Committee. He recognized that there is also a danger that, by further increasing the duties of Parliament, the efficiency of Parliament itself would be impaired: he was dubious as to whether Parliament is the appropriate body to consider closely the actual management of a complex industrial concern, but he was equally concerned that Parliament as well as the public corporation might break down.

There is much to reinforce Mr. Morrison's concern and to suggest that without further decentralization the working of the whole Parliamentary system of Britain may be endangered. Like Lord Reith, he saw clearly that the appointment of a Standing Committee, no matter how carefully its terms of reference were drawn, must raise afresh the whole question of the responsibility for managing and directing the operations of the public corporation. Accountability itself might well become less certain or secure, and as Lord Reith pointed out, a select committee which started as a friendly communicative body might end by investigating and controlling.

The main argument against the Select Committee's recommendation is, however, as the Committee itself admits, that the proposal would impede the working of the nationalized industries and destroy initiative in them. Mr. Morrison, for example, was apprehensive that the existence of such a Parliamentary committee would encourage exactly the conventional, unadventurous type of mind, with its reliance on routine and precedent characteristic of government depart-

ments which Parliament wished to avoid when it created public corporations. Sir Geoffrey Heyworth, chairman of Unilever, Ltd., and a part-time member of the Coal Board, was no less concerned that such a committee might be led inevitably into inquiries on wide decisions of policy, with repercussions that would discourage initiative and the taking of decisions. Any form of detailed control was likely to entail mediocrity or worse, and he looked rather to the public corporations settling down in due course as integrated bodies and developing their own internal controls and their own adequate relationships with the outside public. The more they could develop into autonomous units the better the chances of success.

Sir Geoffrey Heyworth did not conceal the probability that integration might take a very long time. He recognized, too, that autonomy and responsibility to Parliament are scarcely consistent, and it is perhaps natural that a Select Committee should give the greater weight to Parliamentary responsibility. Having rejected any extension of the Parliamentary question as impracticable, the Select Committee reached the conclusion that the only means of providing Parliament with the desired further information for parliamentary accountability was by means of a Parliamentary Committee. Although some witnesses, like Capt. Crookshank and Lord Hurcombe, were in favour of a committee of both Houses of Parliament, and the practicability and even the advantages of such a committee were admitted by Sir Edward Bridges in his evidence, the Select Committee rejected this suggestion and proposed to exclude members of the House of Lords on the rather slender grounds that some of the work of the proposed committee would be of a financial character.

The Select Committee reached this decision with some regret, and the point is one that merits reconsideration in view of the admitted advantages which wider membership would afford. Moreover, it is clear that in its present form the Select Committee's proposal is concerned with the wider context in which the policy of the corporations is determined and not simply with the inquiries into accounts such as the Committee of Public Accounts makes in respect of government departments. The hope is expressed that the proposed committee's dealings with the Boards will lead the Boards to regard it as a body which they can approach to explain their policies and their difficulties. It is strongly recommended that the committee should avoid the investigation of matters which fall into the category of detailed administration.

The Select Committee's proposal is thus for something more than a committee authorized to conduct those inquiries from which the Committee of Public Accounts is debarred. Although the proposed committee would be provided with staff, including an officer of the status of the Comptroller and Auditor General, and it is suggested that the statutory auditors of the corporations, in preparing their annual reports, should give such further information "as may be of use to the Committee and of interest to Parliament"; provided the approach does not differ too widely from those of ordinary professional auditors, the committee has obviously much the same kind of body in mind as the late Lord Lindsay of Birker suggested in a debate on the nationalized industries in 1950. It is anxious to establish friendly and informal relations between the committee and the various boards, though it does not contemplate any-

thing quite so intimate as the Advisory Board, on the model of the University Grants Committee, which Lord Lindsay then suggested.

The Select Committee comments on the limitations which the increasing calls upon the available time of members of the House of Commons place upon any investigation of the nationalized industries by a committee of that House or any sub-committees it may establish. In spite, however, of leanings towards Mr. Morrison's idea of a septennial commission, or Lord Reith's advocacy of a Royal Commission, it does not appear to recognize that this limitation strengthens the argument for bringing in experienced minds from outside the House of Commons. It is content to recommend in effect merely the establishment of a body which will do for the nationalized industries much what the Committee of Public Accounts does for the Departments of State.

The expediency or practicability of such closer financial accountability or the manner in which further information regarding the accounts of the nationalized industries should be supplied to Parliament and to the public is not the vital issue to-day. The purposes of nationalized industry are economic, but it will not be sufficient merely to ensure that the industries are economically efficient: the suspicion or belief that they are inefficient and uneconomic must be dispelled, and the real difficulties arise because we are dealing in a democracy with a system of State-owned monopolies in an economy that is partly free. The information required is such that will give public confidence that monopoly is not abused, or that any abuse will be promptly rectified. Moreover, while the criteria of efficiency have yet to be established, even on practical considerations problems of organization such as size and decentralization have as yet reached no final solution. But, above all, the nationalized industries are differentiated from earlier experiments with the public corporation by the extent to which their policy impinges on public policy. Only within limits can their policy be determined autonomously: inevitably it is determined broadly and to a varying degree by decisions which the Government itself must take. When, as in the matter of fuel, either Minister or Government fails to produce a policy, the responsibility for lack of initiative or co-ordination must still largely rest upon the Government.

On this ground alone, the Royal Commission which Lord Reith advocates so strongly has much to commend it. The meaning of public accountability where the nationalized industries are concerned is still too vague for more than tentative proposals for achieving it to be formulated, and there is neither general agreement as to the exact purposes to be served nor any clear conception as to those purposes. It might well be found, for example, that even if the internal efficiency unit which Mr. Morrison advocates proved practicable, it would yield no substantial advantage commensurate with the effort. The studies which have already been made by the Acton Society Trust have to some extent cleared the ground, but much more is still required in the way of such objective examination; the slackening of Party conflict over the issue may well encourage a wider examination of the many complex issues involved in the decision as to the most appropriate means by which Parliament and the public can be satisfied that the public corporations in general are efficiently run and the public interest truly served.

LABORATORY ANIMALS BUREAU

THE Laboratory Animals Bureau, a unit of the Medical Research Council housed at the Council's laboratories at Holly Hill, Hampstead, London, N.W.3, has published Vol. 1 of its "Collected Papers"*. As Dr. H. J. Parish explains in his foreword to the volume, the Bureau was established in 1947, and its first director was Prof. R. E. Glover, who is now professor of veterinary pathology in the University of Liverpool. After a vigorous start on its useful career under Prof. Glover's experienced guidance, the Bureau is now directed by Dr. W. Lane-Petter, and most research workers who use experimental animals know the work of the Bureau so well that its value needs no emphasis. There will, nevertheless, be many who will welcome the information contained in this volume.

In the first article, Dr. W. Lane-Petter discusses the problems with which the Bureau has to deal, the uses to which experimental animals may be put, the sources of their supply, the problems of procuring them and of maintaining adequate supplies of them, and certain special problems, such as the provision of uniform strains and animals free from infections.

When, however, these problems have been overcome, the further problem remains of managing and properly feeding the animals in the laboratory, and Prof. A. N. Worden deals with this subject of diets and management in an article based on his experience and special study of the subject. Mr. A. E. Mundy, secretary of the Laboratory Technicians Association, which was founded in 1950 to improve the training and status of the assistants who do the important work of looking after laboratory animals, discusses the functions of these assistants, who are, as every research worker will agree, essential factors in all schemes of research which must employ experimental animals. Mr. J. Scarnell discusses the equally important subject of the control of infections of laboratory animals with diseases which may suddenly wreck experimental work. In an article on the provision of animals for research, Dr. J. S. Paterson, of Porton, gives, from his wide experience of both research and the provision of animals for others, a valuable account of the various problems that arise. He discusses the functions of breeders and dealers and the accreditation scheme for commercial breeders that is supervised by the Laboratory Animals Bureau. The Bureau proposes to issue "Collected Papers" each year, and material for inclusion in it may be submitted to the director.

The Bureau has also issued a "Catalogue of Uniform Strains of Laboratory Animals maintained in Great Britain"†. The Catalogue contains details of the origin, pedigree, description and methods of management of laboratory animals maintained in Britain which are "thought to show a reasonable degree of uniformity". It is not claimed that this is a complete list for the whole country, but it is hoped that laboratories that have not yet sent in contributions to the Catalogue will do so in the future. Strains kept by commercial breeders will also be included if they qualify for inclusion. As the Catalogue says: "A useful degree of uniformity is an essential criterion. Hence many of the strains

listed are not strictly inbred, but are random mated in closed population and found by those maintaining them to be sufficiently uniform for their purposes. Whether or not strict sib-mating would increase the degree of uniformity to such a degree as to justify the additional trouble involved is an open question. The answer probably lies in the use to which the animals are to be put. But there can be no doubt that the conditions of management are profoundly important and it is for this reason that much space in the Catalogue is taken up by providing such details."

A feature of these two publications is the picture they give of the humane spirit in action, not only on behalf of the animals with which the Bureau is concerned, but also against disease and the suffering it causes to man and other animals. They also show the valuable results that come when medical men and veterinarians work together in what is, after all, a common field of beneficent activity.

G. LAPAGE

POPULATION OF LONDON, 1951

THE first of the "County Report" series of tables based on the 1951 Census covers the Administrative County of London*. The tables relate mainly to the numbers, distribution according to age, sex and marital condition of the population of the county, and to the structure of the private households and the conditions in which they were housed. In addition, there are tables relating to birthplace and nationality and to the "Social Class" distribution of the male population. Separate figures are given for the City of London and the twenty-eight metropolitan boroughs. Statistics relating to occupations, fertility and other matters on which information was obtained at the Census are not included in the County volumes but will be published in a series of special reports.

The present volume is of general interest as providing a summary account of some of the social changes which have occurred in London during the past twenty years. Many of these changes were either directly due to the Second World War or greatly accelerated by it. The continuous decline in the population of the Administrative County which began between the 1901 and 1911 Censuses has continued. The total population enumerated in the 1951 Census was 3,347,982 as compared with 4,397,003 at the 1931 Census. The estimated resident population of Greater London, however, increased slightly between these Censuses, the proportion in the outer ring having increased from 47 to 60 per cent of the total. The decline in the population of the inner area has been unevenly spread over the various metropolitan boroughs; the weighted average per cent decline was 23.9 per cent, but Poplar, Shoreditch and Stepney lost more than 50 per cent of their 1931 populations, whereas Hampstead, Lewisham and Woolwich gained 7, 3.5 and 0.7 per cent, respectively.

The reduction of the total population and its unequal incidence in different parts of the County, and the unequal incidence of enemy bombing and post-war building have combined to modify the pattern of housing conditions which existed in 1931. Crude averages representing percentages of total population living at given numbers per room may be misleading indicators of the extent of overcrowding.

* General Register Office. Census 1951, England and Wales. County Report, London. Pp. 1+90. (London: H.M.S.O., 1953.) 22s. 6d. net.

* Laboratory Animals Bureau. Collected Papers, 1953. Vol. 1. Pp. 66. 5s.

† Catalogue of Uniform Strains of Laboratory Animals maintained in Great Britain. Pp. III+70. 2s. 6d. (Laboratory Animals Bureau, M.R.C. Laboratories, Holly Hill, London, N.W.3; 1953.)

Nevertheless, it is interesting to see that the percentage of all persons living at more than two per room in the whole County was 2.55 per cent in 1951 against 13.13 per cent in 1931. Some remarkable re-ranking has occurred among the boroughs in respect of this index. The highest figures are recorded in Paddington, Kensington and St. Pancras, whereas in 1931 the worst conditions were found in Finsbury, Shoreditch and Bethnal Green. In general, the rank correlation between the indexes for the two years is fairly high.

The 1951 Census sought to obtain some wholly new information about housing conditions by asking questions about certain household arrangements. The results for London are presented in tables showing (separately) the percentage of households having exclusive use, sharing or being entirely without piped water, cooking stove, kitchen sink, water closet and fixed bath. It is not certain that the results of the new inquiry have come up to the expectations of the designers of the census form either on statistical grounds or as sources of unambiguous information about social conditions in different areas: statistically, the value of the results has apparently been somewhat impaired by misunderstanding of the questions on the part of householders; and sociologically, it appears that the results need to be interpreted in the light of other information about household structure. It is, in fact, not nearly as easy as might have been supposed to decide whether relatively extensive sharing of facilities, or even their absence, is an unambiguous sign of poor social conditions in any given area. Some form of factor analysis might be useful in determining significant criteria from this new material. The new tables showing the distribution of heads of households by age, sex and marital condition might prove specially useful in that connexion.

The report contains tables of the percentage of the male population aged seventeen to nineteen in the various boroughs who were engaged in full-time education. They range from 30 per cent in Hampstead to 1 per cent in Shoreditch, and the figures are highly correlated with the percentage of occupied males in the boroughs who stated their "terminal education age" as being seventeen years or more. The boroughs with high "secondary education" percentages tend also to be those with high proportions of professional workers and those with relatively high proportions of residents from outside London.

FLAX IN NEW ZEALAND

NEW ZEALAND has a native plant, *Phormium tenax*, the leaves of which yield a useful cordage fibre, long known in New Zealand as 'flax' and in commerce as 'New Zealand flax'. This fibre is very different from true flax, the best fibres from *Linum usitatissimum*. The confusion of terms was immaterial before 1940, but in that year New Zealand began to grow crops of the true flax, designating it 'linen flax' to differentiate it from the native fibre. Outside New Zealand it is now customary to refer to the native fibre as 'Phormium' fibre or 'New Zealand hemp'—'hemp' being used as a general term to include all the cordage fibres, while the original hemp fibre from *Cannabis sativa* is described as 'true hemp'.

In Great Britain, as a consequence of the cutting off in 1940 of flax supplies from the Continent of

Europe, the Ministry of Supply appealed to New Zealand to grow fifteen thousand acres of flax to help fill the gap. The response was prompt, favourable and energetic. Fortunately, three years before the War the New Zealand Department of Scientific and Industrial Research had arranged for the officers of its Agronomy Division to make investigations of flax growing and processing in association with the Fields Division of the New Zealand Department of Agriculture; and when the crisis came, the officers were able to advise with confidence where and how the flax could be grown, and what yields of fibre and seed might be expected. But no organization was in being; in so novel a situation the difficulties were immense, for the farmers had no knowledge of the flax crop and the engineering firms had no experience of making the processing machinery. The problem was threefold—to establish an industry, to grow the crop and to process it; and the problem was successfully solved, the success being due to splendid team-work.

A report of how all this was done has been prepared by Mr. J. W. Hadfield, formerly director of the Agronomy Division, N.Z. Department of Scientific and Industrial Research*. To start with, a Linen Flax Management Committee was set up, to which Mr. Hadfield was seconded as director of linen flax production. It was arranged that the Department of Agriculture should organize and control all field operations, the arranging of contracts, sowing and harvesting; that the Marketing Department should handle the export of fibre, tow and seed; and that a Linen Flax Section should be established under the Department of Industries and Commerce to erect mills and carry out all factory operations. The co-operation was secured of the Public Works Department, which undertook the purchase of sites, letting tenders, and supervising the construction of factory buildings and retting tanks. The machinery problem was solved by the help of the Railways Department workshops, which supplied locomotive boilers to the mills and manufactured flax-processing machinery based on European models.

In a few months the new industry was established. The speed with which this co-operative enterprise was developed is revealed by the captions of two photographs in the report: "Instructions to grow flax were received in June 1940. Sowing commenced four months later, and harvesting in January 1941. . . . Flax mills were being built while the crops they were to process were growing. The first fibre was delivered from the mills in March 1941".

Part 1 of the report is a plain record of plans and achievements and describes the fascinating details of how the industry was established, without omitting mention of the inevitable disappointments and criticisms. Part 2 describes the application of the general principles of flax growing to the particular conditions of the seventeen areas in the South Island in which the flax was grown. Part 3 describes the processing methods followed at the mills set up in the various growing areas.

It was inevitable that the hasty but successful improvisation of flax production in 1940 should be carried out without immediate regard to cost; more than thirteen thousand acres were actually sown with flax in 1940, and even greater acreages in succeeding years. But after the War, when it became necessary

* *Linen Flax Fibre Production in New Zealand*. By J. W. Hadfield. Pp. xviii+125. (New Zealand: The Linen Flax Corporation of N.Z., and the N.Z. Departments of Agriculture, Industries and Commerce, and Scientific and Industrial Research, 1953.) n.p.

to effect economies, production was gradually reduced until now only three areas grow the crop. But New Zealand had accomplished what it set out to do; and it made the very welcome addition of 10,274 tons of highly useful flax to the inadequate British supplies.

The report is not only a permanent record of New Zealand's war effort in flax; it is also a mine of information, well printed, lavishly illustrated with excellent photographs, invaluable as a guide to flax production, and indispensable to everyone concerned with flax in New Zealand. In short, Mr. Hadfield is to be congratulated on a very fine publication, as are all who had a share in bringing to a successful conclusion the flax enterprise with which it deals.

A. J. TURNER

BOTANICAL HISTORIOGRAPHY

DR. F. VERDOORN, whose name is well known to botanists, has outlined some of the problems of botanical historiography and has entered the plea that more attention be paid to phytohistory both in its special and more general aspects (*Archives Internationales d'Histoire des Sciences*, 15, 448; 1951; published with the assistance of Unesco). He has also indicated an extensive range of projects to which those who are interested in matters botanical, but who are without laboratory facilities for practical research, might well contribute. Some indication of his point of view is given in the following quotations.

"What is botany? Let us not present a definition which is correct according to the philosophers of science, but let us give the very simple, to some of you perhaps annoying, equation:

Botany = Plants + Men."

"Plants only, we must not forget, do not yield a grain of botany. Yet we will all agree, they are an important part of the equation. Phytohistory, in the widest sense of the word, is the history of the interaction between plants and man's intellectual powers. The history of the vegetable kingdom itself is not phytohistory; depending on our outlook it is historical plant geography, genetics, or paleobotany, but as soon as the human element enters we come into fields, which though they may not all be phytohistory, in the strict sense of the word, will nearly always be closely connected with it, as: ethnobotany, the history of cultivated plants, the history of plant names, etc. . . ."

"Phytohistory aims to contribute to these disciplines, but as far as the phytohistorian is concerned, they are borderlands. His real task is to present an integrated picture of the history of the plant sciences as a whole, of their inter-relations with other sciences and then of the history of each of the branches of scientia amabilia. Thereafter, as we cannot consider any science apart from its makers, we come to other aims, such as studies in the history of regional botany, the history of the major schools of botany, the history of botanic gardens (the only botanical institutions of former generations), the history of botanical expeditions, and last, not least, the history of the individuals—botanici typici et atypici—who made the science of plants what it is to-day. . . ."

"If we now agree that the history of the plant sciences has quite a few possibilities, each of them worth further study and research, we may well consider what we can do towards its promotion. These days there are much more than one hundred thousand

plant scientists in the world. Some of these contribute by research, others by teaching, again others by organizing work. Many are tied up, a good part of the day, by what we call routine tasks, and others who have time for research do not have the equipment or resources. I believe that there are quite a few hundred good plant scientists amongst us to-day who remain utterly non-productive, but who could well apply their training and energy, reducing the frustration from which they are suffering, to serious work in the history of biology. Let us consider, therefore, in the first place, what can individuals do?"

Among these things, Dr. Verdoorn lists studies of ethnobotany, the history of cultivated plants and of plant names, of botany and biology as a whole, of individual botanical disciplines, of local and regional botany, of the major schools of botany, of botanic gardens, of botanical expeditions, and "critical biographies of botanists of the past, which yield basic data needed for work in all the other branches of the history of the plant sciences". The importance and value of international co-operation in advancing the aims of phytohistory are also emphasized.

"The first World War destroyed more international co-operation and goodwill than has ever been rebuilt since 1914. And that brings me to another point. In large countries like the U.S.A., England, France and Germany, where mostly national textbooks are used, even graduate students no longer develop a clear concept of the purely international character of science. Yet, a clear realization of the interdependence of scientists is absolutely necessary to train scientists well, to give them positive and progressive ideas about professional ethics, and to counteract the scientist's instinctive inclination towards petty jealousies which only too easily develop into perennial feuds. Any work in the history of a branch of science which gives our students an acquaintance with preceding generations can help immensely in creating a clear understanding of the mutual international dependence of science and scientists and in building positive ideals among the men who, more than any other group in society, will always be the pioneers in building and reconstructing international relations and co-operation."

GENERATION OF RADIO NOISE BY COSMIC SOURCES

IN a recent paper¹, I concluded that the observed spectrum of general galactic radiation at metre wave-lengths precludes the possibility of a thermal origin by free-free transitions in interstellar gas. The thermal spectrum should have the form $W \propto f^\epsilon$, where W is the observed power at frequency f and ϵ is a function of f which is always positive; the observed value, however, is negative. Another difficulty, pointed out by previous workers, is that accepted estimates of electron densities and temperatures would result in a much lower intensity than observed. The same two objections to a thermal origin apply for the major discrete sources; thus the Cygnus source near 100 Mc./s. has $\epsilon \sim -1.2$ and, furthermore, it is unlikely that the observed intensity could be accounted for with reasonable values of electron density and temperature.

Hoyle has recently² suggested a new process of thermal radio emission from colliding clouds of inter-

stellar gas which he considers overcomes both these difficulties. Electron acceleration is provided, not by individual protons, but by local concentrations of space charge. He claims that, if separation of protons and electrons is complete, then emission is increased by a factor $(v/f)^{1/2}$, where v and n are the electron velocity and density. He considers that a factor of 10^4 might be attained and so account for the observed sources in Cygnus, Cassiopeia and Taurus.

The suggestion provides an interesting extension of free-free emission theory. Under suitable conditions, both a negative value of ϵ and increased emission (above the free-free level) may occur. However, it appears necessary to revise Hoyle's treatment and particularly his conclusions concerning the radio sources.

An error in Hoyle's argument is that he compares his process, not with that of close collisions as in the theory of free-free emission, but with accelerations by small statistical concentrations of charge in volumes of dimensions v/f . Radiation by the latter process is generally so small as to be neglected in free-free theory. The numerical effect of this error is shown by comparing the average emission by a single electron by the proposed process and by free-free emission. First consider an electron moving in a nearly straight line tangential to a sphere of radius b containing n protons per cubic centimetre and no electrons. A pulse of radiation is emitted of duration $\sim 2b/v$ and peak intensity $32\pi^2 e^2 n^2 b^2 / 27 c^2 m^2$ erg sec.⁻¹, e and m being the electron charge (e.s.u.) and mass, and c the velocity of light. This radiation is spread over a frequency-range from zero to about $f = v/2b$, and so the power per unit frequency interval is about $23\pi^2 e^2 n^2 b^2 / c^2 m^2 v$ erg sec.⁻¹ (c./s.)⁻¹. This may be compared with the average power radiated by an electron by free-free emission when the density of protons is also n per cubic centimetre. Such a comparison should rather favour the Hoyle process in the example given, because the electron considered provides the maximum radiation. The majority of electrons will either pass through the sphere of protons or pass it at distances greater than the radius; these will radiate less. Also electrons moving at velocities less than $2bf$ and those passing well outside the sphere have an emission spectrum which is cut off below f and so do not contribute. These effects should more than compensate for the fact that the total number of protons in a given large volume is greater in the free-free than in the Hoyle example given.

The average free-free emission per electron into solid angle 4π is $32(2\pi)^{1/2} A_1(2) e^2 n / 3 c^2 m^2 v$ erg sec.⁻¹ (c./s.)⁻¹, where $A_1(2)$ is a factor proposed by Chapman and Cowling to limit the maximum collision distance for which contributions to the total radiation are considered. For an electron temperature of 10^4 °K. and $n = 1$, its value is 52.6 and the total emission is $1,400 e^2 n / c^2 m^2 v$. Radiation by the Hoyle process exceeds this by a factor of 0.016 $b^2 n$ or 0.002 $(v/f)^{1/2} n$ and not the factor $(v/f)^{1/2} n$ stated by Hoyle.

When applied to discrete source radiation the theory is found inadequate. For example, the intensity and size of the Cygnus source at 100 Mc./s. indicate an average brightness temperature of 4×10^4 °K. If all the electrons in the cloud have velocities of 10^{10} cm. sec.⁻¹, corresponding to a temperature of $\sim 2 \times 10^4$ °K., then the optimum value of b is 50 cm. Assuming a value of $n = 1$ cm.⁻³, then a cloud of thickness (in the line of sight) 10^4 parsecs is necessary to provide optical depth unity

and brightness temperature $\sim 10^4$ °K., somewhat lower than that observed. Throughout the whole of this excessively large gas cloud most of the protons and electrons must be grouped in separate blobs which have at least one dimension about 50 cm. Larger or smaller blobs reduce the radiation at the frequency considered. Roughly similar considerations apply for the Cassiopeia source.

The radio source in Taurus warrants special mention because its spectrum, substantially flat* from 40 Mc./s. to 1,200 Mc./s., is consistent with a thermal (free-free) origin in optically thin gas. However, such an origin would require excessively high values of electron temperature and density* and also of visual radiation†. The position is not retrieved by applying Hoyle's theory. The flatness of the spectrum down to 40 Mc./s. indicates a low optical depth and consequently an electron temperature much higher than the brightness temperature; as for free-free emission, an unacceptably high value of $\sim 4 \times 10^7$ °K. is found. The flat spectrum at 1,000 Mc./s. also necessitates proton concentrations of extremely small dimensions—less than 2 cm. in radius for electron velocities corresponding to a temperature of 4×10^7 °K.

Further quantitative difficulties are met in connection with the method of formation of the space charge concentrations, assumed due to the movement of gas clouds through a magnetic field of strength about 10^{-4} gauss. The maximum electric field which can result is VH/c , where V is the cloud velocity (about 10^4 cm. sec.⁻¹) and H the magnetic field. Electrons accelerated in this field (3×10^{-4} e.s.u.) will give only about 10^{-2} of the radiation found above for the Cygnus source. Again, the radius of gyration of a proton in a magnetic field of strength 10^{-4} gauss is about 10^4 cm. for a proton temperature as low as 10^4 °K. The magnetic field could scarcely form space charge concentrations of dimensions less than 10^4 cm. with random movement $\sim 10^4$ cm.

It would seem that Hoyle's suggestion is not acceptable and that some non-thermal process, involving ordered motions of electrons, must be invoked to account for discrete source radio emission as well as for the general background radiation.

I am indebted to Dr. J. A. Roberts, of this Laboratory, for helpful discussions.

J. H. PIDDINGTON

Division of Radiophysics,

* Greenstein, J. L., and Minkowski, R., *Astrophys. J.*, 118, 1 (1953).

I AM indebted to Dr. J. H. Piddington for directing attention to the omission of a numerical factor in a former communication¹. This arose from the inadvertent use of the usual optical formula for the emission by free-free electronic transitions. This led to the dropping of an important logarithmic factor contained in Dr. Piddington's $A_1(2)$ term. The remaining numerical discrepancy is largely accounted

for by my use of $f \sim v/b$ as an order of magnitude, whereas Dr. Piddington uses $2f \sim v/b$.

Before learning of Dr. Piddington's comments, I had also reached the conclusion that my former suggestion is unworkable, for the reason that I now doubt whether charge separation could occur on a sufficiently fine scale. The smallest unit of distance in an ionized gas is the Debye wave-length λ_D , given by

$$\lambda_D = (kT/8\pi n e^2)^{1/2}, \quad (1)$$

where n is the electron number density and k , T , e have their usual meanings. The regions in which charge separation was supposed to take place (according to the suggestion of my former communication) was less than λ_D by a factor of order 10^3 or 10^2 . It is difficult to see how this could occur, since λ_D is apparently the smallest distance over which one element of material can communicate with another.

It would accordingly seem that the point previously noted—that black-body emission would give intensities comparable with the emission intensities of Cygnus A and the Crab—is probably a coincidence.

Turning to non-thermal processes, there seem to be two schools of thought: the plasma oscillation school and the fast-particle school. From Dr. Piddington's last paragraph one would judge that he belongs to the plasma oscillation school. For my own part, I would favour the other possibility. It seems that progress toward an understanding of the cosmic origin of radio waves may be made by a study of synchrotron-type emission by relativistic electrons¹. This has been discussed by Alfvén and Harlofson², and also mentioned by me³. Since then, certain features of the problem have changed; notably, there is now a much greater certainty concerning the physical nature of the radio sources. This makes it worth again mentioning the advantages possessed by a fast-electron theory.

Before doing so, a criticism must be met. Electrons not only seem to be absent from cosmic rays, but also considerations of the type first discussed by Fermi⁴ would seem to provide a strong reason why relativistic electrons should not be present in interstellar space, namely, that the rate of energy loss from collisions with the interstellar gas clouds is from 10^3 to 10^5 times greater than the rate of gain of energy through 'magnetic collisions'. It may, however, be possible to overcome this discrepancy. The Fermi acceleration mechanism gives a gain-rate that is proportional to the square of the mean random dynamical velocity of the gas masses that carry the magnetic field. Fermi's original calculations were based on a mean velocity of 30 km./sec. In strong radio sources, such as Cassiopeia and Cygnus A, a velocity of 3,000 km./sec. would be more appropriate, thereby increasing the gain-rate by a factor 10^4 —more than sufficient to overcome the discrepancy. It would seem, therefore, that the above-mentioned criticism can be countered. Indeed, the special conditions required for an electron-acceleration mechanism to operate may well prove an advantage, since it apparently explains why the normal interstellar gas is comparatively weak in radio emission and why high dynamical velocities seem always to accompany strong emission, a point that has been emphasized by Minkowski⁵.

Turning now to quantitative aspects of the matter^{1,2}, a relativistic electron of velocity v radiates mainly at frequencies close to the value of v given by

$$v = 4.19 \times 10^8 B \gamma^2 \text{ c./s.}, \quad (2)$$

where B , the magnetic intensity, is in gauss, and $\gamma = (1 - v^2/c^2)^{-1/2}$, so that the electron energy is γ times its rest mass. For $v = 10^8$ c./s., and $B = 10^{-3}$ gauss, the appropriate value of γ is about 150. The power radiated by a relativistic electron is:

$$1.68 \times 10^{-13} B^2 \gamma^4 \text{ ergs/sec.} \quad (3)$$

The latter formula implies that a relativistic electron radiates an appreciable fraction of its energy in radio waves in a time of order

$$5 \times 10^8 B^{-2} \gamma^{-1} \text{ sec.} \quad (4)$$

Using the above relation between γ and v , this may be expressed by saying that an electron radiating a frequency close to v loses an appreciable fraction of its energy in

$$10^{12} B^{-2/3} v^{-1/3} \text{ sec.} \quad (5)$$

Inserting $v = 10^8$ c./s., $B = 10^{-3}$ gauss gives a time of about 10^4 years, which, cosmically speaking, is a very short interval—implying that the present process is a powerful one. Furthermore, it can readily be estimated that if the masses involved in the collision of the Cygnus galaxies are $10^{11} \times$ mass of sun, say, and if the total energy of all relativistic electrons now present within these galaxies is only a fraction, 3×10^{-4} , of the total energy of the collision, then an adequate intensity in the radio band is emitted. Thus the emission is not only rapid when considered from the point of view of an individual electron, but also can be a highly efficient converter into radio energy of the dynamical energy of mass motion of cosmic material.

While the value $B = 10^{-3}$ gauss used above may seem high, it must always be remembered that magnetic intensities much above the normal magnetic intensity in interstellar space are to be expected in high-velocity collisions. In such cases greatly compressed fields are likely to be produced.

It remains to add that these ideas can be put to a test. It is possible, given the energy spectrum of the relativistic electrons, to use the above formulae to obtain the frequency spectrum of the emitted radio waves. Suppose that the number of electrons in the range γ to $\gamma + d\gamma$ ($\gamma \gg 1$) is proportional to $d\gamma/\gamma^2$, this being similar to the normal cosmic ray spectrum. Since each electron emits at a rate proportional to γ^4 , it follows that the total emission by all electrons in the range γ to $\gamma + d\gamma$ is proportional to $d\gamma/\gamma$, which by (2) is proportional to dv/v . Hence the frequency spectrum of the radio waves should follow a dv/v dependence. This may be compared with the observed dependence of about $dv/v^{1.4}$. The agreement is satisfactory in view of uncertainty in the energy spectrum of the electrons.

It is a pleasure in conclusion to express my thanks to Dr. Leverett Davis for a valuable discussion on the subject-matter of the later sections of this letter.

Phototropy of Chlorophyll Solutions

OXYGEN-FREE solutions of chlorophyll in methanol undergo rapid, reversible photochemical changes if they are exposed to a flash of intense light¹. The reversible formation of pairs of radicals, which can be detected by the use of steady, comparatively weak illumination², is apparently preceded by the efficient photochemical production of chlorophyll molecules in a metastable (presumably triplet) state, having a half-life of about 5×10^{-4} sec. Since the experiments, upon which the foregoing conclusions¹ were based, were incomplete and, in many respects, preliminary in character, it was thought worth while to attempt to confirm and to extend them using the method³ of flash photolysis and flash spectroscopy.

The apparatus and techniques were similar to those used by Porter and Windsor⁴ in their investigation of solutions of aromatic hydrocarbons. The purified samples of the chlorophylls and the pheophytin *a* were prepared by Mr. K. Owens at the Department of Chemistry, University of Minnesota. The coproporphyrin tetramethyl ester was kindly given by Dr. Schwartz, of the School of Medicine, University of Minnesota. The several solvents were of commercial origin, of 'Analar' grade when it was available, and were used without further purification.

As is illustrated by Fig. 1, the normal ground-state absorption of these pigments is almost completely absent when the spectrum of the solution is observed immediately after a photolytic flash. While some new regions of absorption appear after flash illumina-

tion of solutions of the chlorophylls or of coproporphyrin, the more obvious change in the absorption spectra is the result of the depopulation of the ground-state. Solutions of pheophytin *a* exhibit the reverse effect; a 4.5×10^{-4} M solution of this pigment in its triplet state is practically opaque throughout the visible ($\lambda < 5800 \text{ \AA}$) and near ultra-violet regions.

Not only were the energies of these flashes comparatively small (125 joules or less), but, in addition, an important fraction of the actinic light was absorbed by the 'Pyrex' walls of the cells which contained the solutions. In a few experiments the energy of the flash was reduced to 75 joules without any appreciable decrease in the photochemical effect. Indeed, quantitative comparisons of the absorption spectra obtained by means of photographic flashes only with the corresponding spectra obtained with weak steady light showed that the photographic flash itself converted a detectable (5 or 10 per cent) fraction of the normal molecules into their triplet states.

The photochemical conversion of chlorophyll into its triplet state is at least as efficient in benzene as it is in methanol. This is in marked contrast to the steady-state formation of the radicals, which occurs⁵ detectably in methanol, acetone, etc., but not when benzene is the solvent. In the preparation of one solution of chlorophyll *b* in benzene (for which we are indebted to Dr. W. F. Watson, of the British Rubber Producers Research Association, Welwyn Garden City), an effort was made to dry the solvent and to exclude moisture from the solution. Although this solution showed the expected reduction in the intensity of its fluorescence⁶, the efficiency of the photochemical formation of the triplet state was not noticeably decreased. Solutions which were saturated with air exhibited virtually no reversible photochemical response to flash illumination (compare refs. 1, 2 and 4).

Qualitative inspection of the spectrograms indicates that the half-life of the principal photochemical transient, which is formed in degassed solutions of these pigments in benzene or methanol, has a value between 2 and 5×10^{-4} sec. In the viscous solvent cyclohexanol, a metastable form of chlorophyll existed in detectable quantities for several milliseconds after the photolytic flash.

The results reported here are qualitatively similar to those obtained⁴ with solutions of aromatic hydrocarbons. They are also consistent with the published¹ interpretation of the phototropic response of methanolic solutions of chlorophyll *b*. A spectral and kinetic analysis of the results, of which that represented in Fig. 1 is a small sample, will be reported elsewhere.

Fig. 1. Series of flash spectra. Numbers are time-intervals between flashes in μsec .; P is photographic flash through solution; S is photographic flash through solvent; F is photolytic flash alone; and Hg is spectrum of mercury-cadmium arc. The solvent was benzene, except in the case of chlorophyll *a*, where it was methanol.

This work is consequent to a series of researches which were supported by the U.S. Office of Naval Research (Project 051,028) at the Department of Chemistry of the University of Minnesota. While the present work was in progress, one of us (R. L.) was a Guggenheim Memorial Foundation Fellow on sabbatical leave from the University of Minnesota. We are also indebted to the British Rayon Research Association for a research grant to one of us (M. W.), and for the loan of apparatus used in this work.

Filter-Paper Chromatographic Analyses of Phosphate Mixtures

PREVIOUS papers^{1,2} from these laboratories described a filter-paper chromatographic procedure for separating and determining the various components of phosphate mixtures. Improved filter paper (Schleicher and Schuell No. 589 Black- and Orange-Ribbon) and other changes have materially increased the accuracy and extended the range of components separated. A revised procedure will be published, but in the meantime an indication of its range and accuracy may be of interest.

Mixtures containing any or all of the following phosphates: ortho-, pyro-, tri-, trimeta-, tetrameta-, are separated into bands by filter-paper chromatography using the solvent tertiary butyl alcohol (80 ml.)-water (20 ml.)-formic acid (5 ml.). The blue phosphomolybdate colour is developed by ultraviolet irradiation. The amount of phosphorus in each band is then determined by a modification³ of the colorimetric procedure described by Boltz and Mellon⁴. Phosphate components of chain-length greater than four phosphorus atoms per molecule remain on the starting line and are grouped together for analytical purposes. The various components are determined with a standard deviation of 0.8 regardless of the percentage present.

Phosphate mixtures of components with one to nine phosphorus atoms per molecule can also be separated chromatographically into bands using the solvent *n*-propanol (60 ml.)-water (20 ml.)-0.88 ammonium hydroxide (20 ml.). However, the separation is not so clearly defined and thus the analyses are not considered to be as accurate, even though the precision is ± 1 per cent. The accuracy cannot be checked since pure samples of these polyphosphates are not available at present.

Electrophoresis of Group-Specific Extracts of Streptococci

WHILE it is known that differences in the make-up of large molecules can be detected immunologically when the molecules are chemically and physically indistinguishable, it is also true that different groups of bacteria show many differences besides their immunological reactions. It is to be anticipated that the hydrochloric acid extracts which are used as antigens in precipitin reactions will be complex mixtures, and though they show the characteristic immunologically specific reactions it will not be surprising if grosser differences appear. The number and electrophoretic behaviour of the colloids present may constitute such differences. This was tested by examining extracts of nine strains from five serological¹ groups of streptococci. The strains were 28/USA of Group A, C104 and NCTC8181 (*Streptococcus agalactiae*) group B, Pearl 11 (*Str. bovis*) and 775 (*Str. faecalis*) group D, C24B and 4678 (*Str. infrequens*) group E, and H14 (*Str. lactis*) and H19 (*Str. cremoris*) of group N².

Hydrochloric acid extracts were prepared by the method of Lancefield¹ and were concentrated by ethanol precipitation; their specificity was established in precipitin ring tests with immune sera for each of the relevant serological groups. The precipitin tests were made by Shattock's³ technique and were read repeatedly between 1 and 10 min., and the negatives again after 15 and 30 min.

The extracts were submitted to electrophoresis by the usual free-boundary technique. The electrophoresis of the first batch of extracts (Fig. 1) was carried out in 0.01 M potassium phosphate, pH 8.4, containing lithium chloride at a concentration of 0.05 M. The precipitates from the ethanol treatment were suspended in the buffer and allowed to dialyse in 'Viking' tubing against the same buffer for a minimum of forty-four hours with at least three changes of buffer. The short dialyses were done at room temperature with thymol as a preservative. Frequently, dialysis was carried on for longer at 10° C. or below.

Occasionally small amounts of precipitate failed to dissolve. Frequently, the solutions were opalescent. They were subjected to a thorough centrifuging, which, however, diminished the opalescence only slightly. The electrophoretic diagrams were therefore of low contrast; one peak in this set was difficult to interpret (this has been shown with a serrated edge in Fig. 1) and another solution was impossible to analyse.

Similar remarks apply in general to the second set (Fig. 2), in which 0.05 M aminoacetic acid adjusted to pH 9.0 was used.

Tracings of the electrophoresis diagrams together with relevant data are shown in the figures. One of those for group E in Fig. 2 is notable for showing negative density gradients on the descending side. For this reason the run was stopped after only ten minutes. The buffer conductivities for the calculation of potential gradients have been determined since the experiment. Rough measurements carried out at the time indicated that in the glycine buffer all the extracts had a higher conductivity than the buffer alone. The diagrams show that the conditions were not ideal for quantitative electrophoretic analysis, but they were maintained because qualitative differences may sometimes be observed more easily under such conditions⁴.

It may be seen from the figures that interesting differences in the electrophoretic pictures occur,

though group differences as opposed to strain differences are not immediately apparent. It is clear that many more comparisons would be needed to recognize these, if, indeed, they do actually exist. Electrophoresis may, however, be of greater value in the

Paper Electrophoresis of the Oligosaccharides synthesized from Sucrose by Yeast Invertase

The interesting suggestion that the oligosaccharides

formed from sucrose may be the precursors of polysaccharides such as inulin and levan requires verification by the establishment of the identity and type of linkage of each of these compounds¹. The recent discovery of their presence in plant extracts² and human urine³ is a certain indication of their significance in metabolic processes.

Good progress, mainly by chromatographic techniques, has latterly been made in the identification of most of the compounds produced from sucrose by yeast invertase⁴. It was, however, found that a few problems of separation were left unsolvable by chromatography. The application of the recently described⁵ high-voltage technique of electrophoresis to this group of compounds has proved a definite advance on the paper chromatographic technique and has provided an alternative tool for checking the homogeneity of 'chromatographically pure' fractions.

Incompletely hydrolysed sucrose solution was prepared according to our procedure⁶ and diluted to one-tenth of the original concentration before application to the paper strip. The accompanying figure illustrates results obtained by the electrophoretic technique in comparison with the paper chromatographic method. The electrogram *C* shows eight distinctly separated spots, while the chromatogram *A* shows only six spots.

Under our conditions of incubation component IV was not formed in any detectable quantity. Throughout this communication the nomenclature suggested by previous workers^{7,8} is followed. It had been observed⁸ that on chromatograms the sucrose spot obscured another spot representing component V, which was detected by its reducing power and appeared to consist of two fructose residues. The leading edges of a number of sucrose spots were therefore extracted with water and subjected to paper electrophoresis. On development

⁴ Svensson, H., Ark. Kemi Min. Geol., 17 A, 1 (1943).

Electrophoresis of oligosaccharides. (A) Chromatogram of a sucrose solution incompletely hydrolysed by yeast invertase. Conditions: 5 μ l. of 50 per cent (w/w) sucrose sol. run for 48 hr. with mixture α -propanol-ethyl acetate-water (7:1:2, by vol.) sprayed with α -naphthol and phosphoric acid for kestose-containing compounds. F.G. is fructosyl-glycerol. (B) Chromatogram of some oligosaccharides run under the same conditions. Mould D.F. is an assumed difructose-compound produced by mould invertase. (C) Electrophoresis of incompletely hydrolysed sucrose solution. Conditions: 40 V./cm. 20-28 m.a.m.p. Whatman No. 3MM, 2 $\times$ 23 $\frac{1}{2}$ in. strip, 0.05 M sodium borate solution, pH 9.2, 5 μ l. of 5 per cent (w/w) hydrolysed sucrose solution applied 6 in. from cathode end, 3 hr., same spray as in (A). (D) Run under the same conditions for 2 $\frac{1}{2}$ hr., 50 μ gm. of sucrose. (E) Run under the same conditions for 2 $\frac{1}{2}$ hr. (F) Applied in centre of strip and run under identical conditions for 3 hr., 50 μ gm. of kestose

with α -naphthol and phosphoric acid a series of three spots could be seen (D). The two faster spots correspond to two spots on C, while the faint spot is not made visible owing to its low concentration in the mixture applied to C. It thus appears that component V is not homogeneous but consists of two major and at least one minor constituent. Their identity has not yet been established. A sample of a difructose-compound produced from sucrose by mould invertase (supplied by Dr. J. S. D. Bacon), when examined electrophoretically, showed a similar pattern of three spots, the only apparent difference being that the second component was present in a far lower concentration (E). Chromatographic-

ally, there is no distinction between these two 'compounds', as can be seen in B.

While examining by electrophoresis the homogeneity of chromatographically separated fractions, it was found that component II yielded one major spot and one minor spot of a mobility slightly lower than that of kestose (F and B). Bacon⁴ succeeded in separating II by the gradient elution technique on a carbon-'Calite' column, and named the two components II₁ and II₂. Kestose, II₁ and II₂ are all trisaccharides. Samples of his compounds were examined electrophoretically, found to be homogeneous, and were later used as controls. II₁ does not appear to be separated in C, as the small difference in mobilities of II₁ and kestose would necessitate a considerably longer time of running, at the end of which the faster-moving components will have left the anode end of the strip.

In the earlier stages of the investigation it was assumed not only that II is homogeneous but that, judging by its paper chromatographic behaviour, it might be identical with component α_1 produced by mould invertase⁵. This would have provided a quicker route for the preparation of a large quantity of II₁ for the study of its structure. It could be shown, however, electrophoretically that the mobility of α_1 is distinct from that of II₁ and similar to that of II₂ (F). The fastest spot in A was found to correspond to the spot ahead of sucrose in C and to be a compound of fructose with glycerol, probably fructosyl-glycerol. This component had previously been observed⁶, and its formation depends on the presence of glycerol in the invertase preparation.

At the high voltage applied the electro-osmotic effect is considerable, as shown in F, counteracting the migration of the sugar-borate complexes towards the anode and making them appear to travel towards the opposite electrode. This effect might to some extent interfere with the determination of true values of mobilities, but apparently does not obstruct the reproducibility of the separations. Whatman No. 3MM paper was found in this case to give the best results with regard to loading capacity and regularity of spots. Although the thicker paper meant higher current values, the cooling system proved to be adequate in dealing with an energy dissipation of 60 watts. With more efficient cooling the final current value was recently limited to 25 m.a.m.p.

Thiaminase from Fresh-Water, Brackish-Water and Salt-Water Fish

It has already been reported¹ that there might exist in fish more than one enzyme possessing thiaminase activity. In view of this observation, it was thought of interest to investigate thiaminases from different varieties of fish.

For the present investigation, the fishes were classified into three broad groups: (i) fresh-water fish; (ii) brackish-water fish; and (iii) salt-water fish. The following varieties (two from each group) were studied.

Source	Name of fish
1. Fresh-water fish	Khavale (<i>Barbus varanus</i>) (<i>Labeo bagrus</i>) (Sykes)
2. Brackish-water fish	Vamahl (<i>Mugil</i> sp.) Tol (<i>Hemichromis ornithopterus</i>)
3. Salt-water fish	Mandoli (<i>Ostrea edulis</i>) Pedve (<i>Sardinella tibrata</i>)

The whole fish was ground in a mortar and the enzyme extracted with water. The extracts were filtered and the filtrates were tested for activity. The effect of hydrogen ion concentration on the inactivation of thiamine by thiaminases from different varieties of fish was studied. The experiments were carried out between pH 3.0 and 7.0, using acetate and phosphate buffers respectively. The reaction mixture consisted of 5 ml. of water extract plus 5 ml. of the buffer and 25 µgm. of thiamine. The reaction mixture was incubated overnight for 16 hr. at room temperature (28° C.) with toluene as a preservative. Thiamine left over at the end of this period was estimated by the thiochrome method². The results of typical experiments are shown in Fig. 1. Although six species of fish were examined for thiaminase activity only three are represented graphically for the sake of convenience. The other three species also showed a similar pattern of pH activity relationship.

It is evident from the above results that the fresh-water fish contains thiaminase having optimum activity only at pH 7.0 or above. The graph shows that the fresh-water fish contains only one enzyme exhibiting thiaminase activity. These results are in full agreement with those reported by earlier workers. While working with a carp, which is a fresh-water fish, Woolley *et al.*³ reported optimum activity at

Fig. 1. Effect of pH on thiaminase from fish: (a) *Barbus varanus*, fresh-water fish, (b) *Mugil* sp., brackish-water fish, (c) *Ostrea edulis*, salt-water fish

pH 8.0, Sealock *et al.*⁴ at pH 9.1 and Bhagwat *et al.*⁵ at pH 6.0.

The curves for brackish-water fish and salt-water fish closely resemble each other, but vary remarkably from that obtained for the fresh-water fish. In the case of brackish- and salt-water fish, there are three different hydrogen ion concentrations (namely, pH 3.6, 5.6 and 7.0) at which the enzyme exhibits optimum activity. This confirms our previous observation¹. From the above results it appears that there are at least two thiaminases having optimum activity: (i) in the neutral or slightly alkaline range; and (ii) in the acid range. This difference may be due to the composition of the water and other environmental factors.

Extracts from all the three different varieties of fish were dialysed, and it was observed that the enzymes having optimum activity at pH 3.6, 5.6 and 7.0 from brackish- and salt-water fish and the enzyme from the fresh-water variety lost the greater part of their activity. The activity, however, could be restored in all cases by the addition of boiled original extract, thus confirming the presence of a coenzyme in all cases, as reported in a review article by Yudkin⁶.

The effect of the addition of certain metallic salts, namely, sulphates of copper, zinc, manganese, magnesium, iron, cobalt and nickel (*M*/100 concentration) to the dialysed extract was studied, and it was found that only manganese and cobalt salts could restore the activity of the enzyme exhibiting optimum activity at pH 3.6 and 5.6. None of these salts could, however, restore the activity of the enzyme exhibiting optimum activity at pH 7.0 from brackish- and salt-water fish, or that of the enzyme from fresh-water fish. This confirms our previous observation that the enzyme having optimum activity at pH 7.0 is altogether different from those having optimum activity at pH 3.6 and 5.6.

Fractional precipitation with organic solvents such as acetone, alcohol and dioxan failed to separate the three thiaminases; all three could be precipitated at 50 per cent saturation of ammonium sulphate. Adsorption-elution procedures were tried with a

number of adsorbents. All the thiaminases are adsorbed on fuller's earth, alumina C γ and bentonite. A number of solvents were tried, but none of them could selectively separate the three enzymes. Work on the separation of the three enzymes by paper chromatography is in progress.

We wish to thank the Indian Council of Medical Research, New Delhi, for the award of a research fellowship to one of us (S. T. D.) and to the Director of Fisheries, Government of Bombay, for identifying the fish.

Free Amino-Acids in the Yolk during the Development of the Chick

THE progressive appearance of free amino-acids in the yolk during the development of the chick have been examined by paper chromatography, and we have observed that the density of the spots, from comparable aliquots, of yolks from fertilized hen's eggs increased from the fourth to the tenth day and decreased after this to the twelfth. To test these observations by an additional approach, similar samples were chromatographed on 'Dowex' and the results are reported here.

Whole yolks of fertilized hen's eggs at the stages of embryonic development indicated were precipitated with a solution containing 2 ml. of 1.0 N hydrochloric acid per 100 ml. acetone. For each yolk approximately 150 ml. of acetone was added. The water in the yolk made this aqueous acetone approximately 80 per cent acetone. The extracts were evaporated at 25°C. under moving air. The dried residues were dissolved in known amounts of citrate buffer, pH 3.4, and, after centrifugation, aliquots representing approximately 10 gm. of yolk were chromatographed on 100 cm. and 15 cm. 'Dowex' columns¹. Proline was introduced into some extracts in order to relate other chromatographic positions with the increased absorption at

Table 1. FREE AMINO-ACIDS IN THE YOLK OF THE FERTILIZED HEN'S EGG AT SEVERAL STAGES OF EMBRYONIC GROWTH

Amino-acid	8	Days of incubation 6 (μ M per aliquot*)	9	12
Threonine	—	0.65	3.0	0.91
Serine	0.35	1.9	5.0	1.8
Glutamic	0.22	0.46	3.2	0.79
Proline	—	1.6	6.8	0.40
Glycine	—	0.41	4.4	—
Alanine	—	0.61	3.7	0.71
Cystine	—	0.56	0.99	0.75
Valine	—	0.51	1.3	1.1

Leucine	2.2	2.0	4.0	1.0
Tyrosine phenylalanine	2.3	1.3	5.3	1.3
Lysine†	0.67	0.69	2	1.0
Arginine†	—	—	1.5	—
Methionine	0.10	0.20	0.20	—

* Each aliquot represents the free amino-acids from 10 gm. yolk.
† Released from 15-cm. 'Dowex' columns

Fig. 1. Chromatographic separation of the amino-acids quantitatively released from 100-cm. columns of 'Dowex 50' with buffered solvents. A and B represent samples of yolks from fertilized eggs incubated three and six days respectively. Dotted lines indicate measurements at 420 m μ . 60 per cent of the peak shown for proline in B was due to introduced proline (see text). Methionine (unlabelled) is on left of isoleucine. The temperature on these columns was at all times less than 75°, and therefore the emergence of tyrosine and phenylalanine together in the effluent is not a limitation of the published procedure (ref. 1).

420 m μ that characterized the reaction product when this amino-acid is treated with ninhydrin. The paper chromatography followed the procedure of Levy and Chung². Acids were identified by relating the chromatographic positions of known acids with those of the unknown acids, and by comparing the effluent acids from aliquots of the extracts examined on 'Dowex' columns with the distribution of the amino-acids on paper from the corresponding sample.

Typical chromatograms are shown in Fig. 1. The free amino-acids (Table 1) increase to the ninth day, but decrease on the twelfth day. Presumably these changes are related to the progressive proteolysis of the yolks, an observation not previously described for the yolk³ of the hen's egg, although it is known to contain three proteinases⁴. The absence of fixed relative quantities of amino-acids characterizing the intervals sampled is interesting. Similar observations were made on the basis of the density of the spots on paper chromatograms of samples of yolks from the fourth to the twelfth day. It is unlikely that the relative concentration of amino-acids appearing on the ninth, as contrasted with the twelfth, day are a function of proteolysis alone. Such changes are doubtless related to the demands in protein synthesis during the development of the chick.

This investigation was supported in part by a research grant from the National Cancer Institute of the National Institutes of Health, United States Public Health Service.

Waste of Carbon and of Energy in Nitrogen Excretion

It is commonly accepted that, in nitrogen excretion, urea—and more especially uric acid—are wasteful to the organism in that they involve the loss of carbon and, moreover, chemical energy (see, for example, Needham¹). Compared with ammonia, these substances are regarded as inefficient and as only resorted to under the exigencies of water conservation. Table 1 summarizes data from the literature, from which it is seen that, per nitrogen atom, the order of carbon waste (column c) is:

ammonia < urea < uric acid (or 0; 0.5; 1.25).

But the amounts involved are scarcely significant; for example, for a man to excrete 30 gm. urea plus 0.7 gm. uric acid per day (Starling²) means the loss of 6.25 gm. carbon, which can be made up by the intake of 15.6 gm. glucose or equivalent. Similar calculations may be made for other non-ammonotelic animals.

In considering the energy factor, Needham quotes heat of combustion values for these three nitrogenous compounds in kcal./mole (column d), where the waste is in the order:

ammonia < urea < uric acid (or 1:1.69:5.11);

but it will be more pertinent to examine the figures for kcal./mole/nitrogen atom (column e), in which case the heat of combustion values appear in the order:

urea < ammonia < uric acid (or 1:1.18:1.51).

However, it may be considered that the free energy of formation gives a truer indication of the energy relationships to the organism, and the order for these values is:

ammonia < urea < uric acid (or 1:7.73:14.52),

when calculated as kcal./mole (column f), and

ammonia < uric acid < urea (or 1:3.63:3.87),

when calculated as kcal./mole/nitrogen atom (column g).

Table 1

	a	b	c	d*	e	f†	g
		Empirical formula	Ratio C/N	— ΔH Heat of combustion (kcal./mole)	Heat of combustion (kcal./mole/N atom)	— ΔG Free energy of formation (kcal./mole)	Free energy of formation (kcal./mole/N atom)
Ammonia		NH ₃	—	90	90	6.3	6.3
Urea		CO(NH ₂) ₂	0.5	163	76	48.7	24.4
Uric acid		C ₅ H ₄ N ₄ O ₆	1.25	460	115	91.46	23.87

* The figures in column d are given in Needham as cal./mole, but they should obviously read kcal./mole.

† The figures in column f refer to the aqueous state for ammonia (Partington, ref. 3) and for urea (Parks and Huffman, ref. 4); the figure for uric acid is for the solid state (Partington), and in view of the low solubility in water the figure for the aqueous state will be slightly reduced.

Thus it may be concluded that: (i) ammonia is the most advantageous from the point of view of economy in carbon and in energy (except slightly in — ΔH calculated per nitrogen atom); (ii) urea wastes less carbon than does uric acid, but the amount is unlikely to be significant in either case; (iii) urea is approximately as wasteful as uric acid, and both are somewhat more wasteful than ammonia, in terms of — ΔG calculated per nitrogen atom, but the waste of chemical energy is not nearly as great as is generally implied.

It is suggested that the question of which nitrogenous end-product is resorted to may still be con-

sidered as depending on the abundance of the water supply of the organism, but that urea and uric acid excretion are not as disadvantageous as is sometimes expressed in the literature. Any disadvantage in terms of carbon and energy waste is far outweighed by the advantages conferred by ureo- or urico-tely.

Stimulation of Certain Bacteria by Raw Milk

ALTHOUGH raw milk contains bacteriostatic substances, certain concentrations of it actually stimulate some micro-organisms such as *Streptococcus agalactiae* and *Str. lactis*¹. Since the bacteriostatic properties appear fairly constant², variations in stimulatory properties may account for the observations of seasonal variation in the growth-rate of micro-organisms in milk³.

Using cows infected in one or more quarters of the udder with mastitis, it has been found that milk from infected quarters is more stimulatory to *Str. agalactiae* than milk from non-infected quarters of the same udder.

Colostrum taken just before cows calved had a very high stimulatory effect, whereas just after calving the effect was much less. This is interesting, as it is known that cows are more susceptible to mastitis during the dry period.

A range of amino-acids and growth-factors was examined to discover whether any had stimulatory properties like those of raw milk. Only certain sulphur compounds gave positive results. Sodium sulphide and thioglycollic acid were stimulatory at concentrations down to $10^{-3} M$; cystine and cysteine were still effective at $10^{-4} M$. Sodium sulphate was without effect.

It is suggested, therefore, that the concentration of certain sulphur compounds normally present in traces in milk affects markedly the rate of growth of some micro-organisms. The same factor may also control the susceptibility of cows to mastitis.

This work, which was carried out during the tenure of a British Council Scholarship at the National Institute for Research in Dairying, was part of an investigation on the inhibitory and stimulatory properties of milk.

Separation of Pigment Cells of Cacao

THE purple pigment in the cotyledons of unfermented Forastero cacao is distributed in separate cells which are readily seen in cut sections. These separate cells can also be seen in sections from the Pale Criollo cacaos, though they are not coloured purple.

During the fermentation process, the contents of these cells dissolve, and diffuse throughout the cotyledons and into the testa of the bean. Some constituents of the substance of the cells undergo oxidative and other changes, and some of the material is lost into the 'sweetings' which drain from the fermenting beans.

When the freshly harvested beans are dried rapidly, there is no diffusion of the substance of the pigment cells, which can be seen apparently intact in sections of the cotyledons of beans dried in this way. These dried pigment cells have a higher density than the other cells of the tissue, and a separation of them has been effected as follows.

The dried beans are freed from testa and radicle, the cotyledons crushed to a suitable degree—a household coffee mill with the finest setting has been found suitable—and the ground mass suspended in petrol. The fat is dissolved, and of the mixture of insoluble suspended matter, the protein and starch are almost completely removed by sedimentation and decantation. The heavier mixture of free pigment cells and coarse tissue, mainly cellulose, is then sifted through a 240-mesh sieve suspended in petrol. The coarse, less dense, tissue is held on the sieve and is rejected; the free pigment cells pass through the sieve. Further careful sedimentation and decantation, preferably from a shallow dish, give a final product of separated pigment cells with about 5 per cent of adherent extraneous matter which is not removed by further washing with petrol.

The whole amount of the pigment cells in the cotyledons is not recovered in this way; some cells are too firmly attached to the lighter tissue and do not pass through the fine sieve. When carefully dried beans are used, about one-half of the total can be recovered as separated cells.

These dried pigment cells are dark purple, almost black, in the case of West African Amelonado cacao, somewhat lighter and redder purple in the case of most West Indian and South American cacaos, and a light puce colour in the case of East Indian and other 'white' Criollo cacaos.

The pigment cells are rather larger than the other cells of the dried cotyledons, the maximum lengths being about 50μ and $35\text{--}40\mu$ respectively.

It has been found that the whole of the purin substances, and probably the whole of the polyphenolic substances, in the cotyledons are concentrated in these pigment cells. They dissolve almost completely in water, giving a solution of pH 6.5–6.7, the same as that recorded for an aqueous extract of the fresh whole cotyledons¹.

The proportion of pigment cells in the total tissue of the cotyledons has been determined from a comparison of theobromine contents, and found to vary from 11 to 13 per cent by weight in the air-dry cotyledons. This compares well with the figure of about 10 per cent by count quoted by Knapp².

This separation of the polyphenolic and purin constituents from the other components of the bean provides a new and better approach to the study of these constituents, particularly the polyphenols.

Solutions can be prepared which are free from extractives from other components of the bean, and are less labile than solutions from extracts of the whole cotyledon.

This is being applied, and analyses obtained giving comparisons between cacaos from different sources.

This work was carried out in the laboratories of Messrs. Rowntree and Co., Ltd., York, and is communicated by permission of the directors.

Intra-arterial Injection of Methylene Blue for Staining Nerve Endings in Striated Muscles

THE difficulty of staining nerve endings with methylene blue is well known. I have found that intra-arterial injection of methylene blue in an anesthetized animal consistently stained the nerve endings of striated muscles with greater uniformity than was possible by intravenous injection or the local infiltration of methylene blue. The method used is as follows.

Under ether anaesthesia, a convenient artery supplying the muscles the nerve endings of which are to be stained (for example, the femoral artery for staining the endings in the muscles of the hind-legs) is exposed and dissected free. The staining fluid consists of 0.25 per cent zinc-free methylene blue in a solution of 0.8 per cent sodium chloride, 0.2 per cent glucose, 0.02 per cent magnesium bromide, buffered to a pH of 6 with phosphate buffer¹, with 1 mgm. of hyaluronidase² added to 20 ml. of the solution immediately before use. The fluid is warmed to the body temperature and slowly injected into the exposed artery by means of a syringe and a needle of suitable size until the skin over the injected part turns deep blue in colour. The amount required for this depends, of course, on the dimension of the area to be injected, hence preliminary trials are usually necessary to find the right dose. In adult rats and chickens, injections of about 4 and 40 ml. respectively into the femoral artery stained the nerve endings in the hind-legs. The tendency at the beginning is to inject too little, but an overdose results in the undesirable staining of the blood cell and muscle nuclei or in the death of the animal.

After injection, arterial bleeding from the withdrawal of the needle is stopped by clamping the artery with artery forceps, and the animal is kept alive under anaesthesia for 10 min. before killing it by bleeding. The muscles are removed, the large muscles are sliced to about 3 mm. in thickness, and they are suspended on hooks in an oxygen chamber kept damp by a piece of wet cotton-wool. After about half an hour the 'blued' muscles are examined under the microscope and pieces that contain stained nerves and endings are selected for fixation overnight in chilled 8 per cent ammonium molybdate solution. Serial frozen sections are cut, rapidly dehydrated in chilled *n*-butyl alcohol, cleared in xylene and mounted in Canada balsam.

This method had been successfully used in staining the nerve endings of the leg muscles of rat, rabbit,

Two types of nerve endings in *M. extensor et adductor digitorum* of the second and third wing digits of the chicken, stained by the injection of methylene blue into the brachial artery. ($\times 800$)

frog and chicken (Figs. 1 and 2). The endings in the intercostal and diaphragmatic muscles of rats have also been demonstrated by retrograde injection through the carotid artery into the aorta.

Conductivities of Polyelectrolyte Solutions at High Frequencies

THE electrical conductivity of aqueous solutions of electrolytes increases with increasing frequency of alternating current. For simple electrolytes such as potassium chloride, this increase in conductivity does not become apparent until the frequency is of the order of 10 Mc./s.

The explanation of this phenomenon is given by the Debye-Hückel theory of electrolytes, that when the time of relaxation of the ionic atmosphere is greater than the period of the alternating current used, then an increase in conductivity of the solution will occur. It was found, when experiments were being carried out on aqueous solutions of the polyelectrolyte sodium polymethacrylate, that an increase in conductivity occurred at a much lower frequency than with the corresponding concentration of potassium chloride solution.

If we consider an assembly of uncoiled long-chain polyions in an alternating electric field, the effect of the latter will be to cause displacements of the polyions or segments of polyions within their cylindrical ionic atmospheres. The rate of recovery from displacements in the direction of the axis will be relatively slow, since the ionic atmosphere will retain its cylindrical symmetry, and the restoring force will therefore be small.

As regards displacements resolved at right angles to the axis of the polyion, one would expect the time of relaxation to be similar to that of a small spherical ion. The summation of the various displacements should clearly result in the appearance of a frequency effect at a lower frequency than is observed with small spherical ions.

The apparatus for proving that the effect occurred consisted of a variable-frequency oscillator giving a constant voltage output. The current was passed through the conductivity cell, which was in series with a variable resistance, and a high-frequency milliammeter. At a particular frequency, if the conductivity decreased, then the series resistance could be varied until the same ampere reading on the high-

frequency milliammeter was noted. The adjusted reading on the variable resistance gave an indication of whether or not an increase in conductivity had occurred.

The readings from the instrument for the sodium polymethacrylate solutions were compared with standard potassium chloride solution, keeping all the conditions in both experiments identical, so that any stray capacitance effects were the same in both sets of solutions. This showed that the conductivity of sodium polymethacrylate solutions began to increase at a much lower frequency, that is, at about 0.1 Mc./s.

Thermal Conductivity Measurements on Inert Media using Internal Calorimetry

INTERNAL calorimetry¹, developed for the measurement of blood flow, is basically a method for thermal conductivity determination. It uses a fine-gauge heated thermocouple embedded in the organ or medium under examination. In simple media a steady heating current applied to the filament raises the temperature recorded by the thermocouple. Temperature equilibration is rapid. Heat exchanges² are governed by Carslaw's equation³: $I^2 R = 4\pi r \theta k$, where k is the thermal conductivity of the medium, I the heating current, R the resistance of the heater, r the radius of a thermodynamically equivalent sphere and θ the temperature increment. Thus the relation between I^2 and θ is linear when k is constant; $4\pi r/R$ is a constant for any given recorder and constitutes its standardization factor (F), the experimental determination of which has been fully described elsewhere⁴.

The accuracy of the method was tested using various media. All determinations were carried out in a temperature-controlled room ($20^\circ \pm 1^\circ \text{C}$), with the medium in a water-bath at 20°C . In each case the relation between I^2 and θ was plotted from 0° to 3°C . at intervals of 0.2°deg . Knowing F , the thermal conductivity, k , was readily determined. The accuracy with solids and semi-solids was good, but was greatly reduced in liquids. The following values represent an average of three separate determinations, and are compared with figures quoted in the "International Critical Tables".

Substance	k (observed)	k (I.C.T.)
'Vaseline' (at 0°C)	4.55×10^{-4}	4.40×10^{-4}
Paraffin wax (m.p. 50°C)	6.45×10^{-4}	6.0×10^{-4}
Liquid paraffin	3.56×10^{-4}	$3.11 - 4.54 \times 10^{-4}$
Glycerol	6.72×10^{-4}	$6.58 - 7.41 \times 10^{-4}$
Water	13.6×10^{-4}	$13.86 - 14.23 \times 10^{-4}$

To accelerate equilibration it was usual to overheat the filament, then cool to the required temperature increment. In most media, equilibrium, once reached, was thereafter maintained indefinitely.

In 'Vaseline', however, it was found that about 20 sec. after cooling to the appropriate temperature a slow upward temperature drift began. Experiments were therefore carried out in which a steady current (such as would theoretically raise the temperature of the heater by 1 deg.) was suddenly applied to the recorder*. In 5 per cent gelatin gel, liquid paraffin, paraffin wax and glycerol no further temperature drift occurred after the calculated 1 deg. increment had taken place, but in 'Vaseline' the upward drift continued during the whole period of recording. In one experiment the temperature rose steadily during 30 min. to a value of 1.78 deg. higher than the theoretical equilibrium.

Read and Lloyd⁶ showed that a marked drop in thermal conductivity in tri-nitro-toluene occurred at or near the melting point. It seemed possible that a similar alteration in the thermal conductivity of some of the hydrocarbon components melting at 20–21° C. might explain the present findings. 'Vaseline' was stored in a refrigerator for a week, when its temperature was 4° C.; this temperature was probably lower than the melting point of any of the components. With the 'Vaseline' in a freezing mixture a steady heating current was applied as before. No temperature drift now occurred; thermal equilibrium was rapidly reached and maintained throughout the recording period.

These experiments emphasize the suitability of internal calorimetry for measuring thermal conductivity in non-fluid media. They also give fresh evidence suggestive of changes in thermal conductivity in a hydrocarbon mixture at about the melting point.

Energy Requirements for Ion Transport in Steady-State Systems

SEVERAL investigators^{1–3} have attempted to calculate the energy required to maintain steady-state exchanges of ions between animal tissues and their environments. Thus, Krebs, Eggleston and Turner¹ concluded that about 2.5 per cent of the respiratory energy was required for potassium exchange in brain cortex slices at 40° C., and Bernstein² calculated that the steady-state exchanges of sodium and potassium in red blood cells at 37° C. may require up to one-third of the free energy from glycolysis. These calculations^{1,2} were based on the assumptions that there was 100 per cent efficiency in the utilization of metabolic energy for ion transport, that the losses and gains of the same ion were independent, and that the movements of different ions were also independent of one another. These assumptions are not necessarily valid.

The value obtained for the free energy change in the net transport of 1 mole of ion from one electrochemical potential to another represents the minimum

energy requirement in a biological system. If some of the potentially available energy is not used in doing useful work, then the actual energy requirement will be more than that calculated from thermodynamics. In addition, the exchanges of one ion for another of the same kind in a steady-state system may not require any expenditure of energy since no net transport occurs^{3–5}. This is the case in a Donnan system and an ion-exchange resin in equilibrium with an aqueous salt solution. Harris⁶ has, in fact, shown that part of the to-and-fro movements of sodium and potassium in red blood cells takes place without a supply of energy. The migrations of different ions may also be linked⁷. The figures given above, obtained by the application of kinetic data on steady-state exchanges to thermodynamic data for net transport, are therefore maximum values of minimum ones and may have no significance.

This method of calculation has been applied to results⁸ on the exchange of sodium and potassium in guinea pig kidney cortex slices in steady states *in vitro*. It leads to apparently reasonable conclusions for respiring tissue (see also Krebs and co-workers¹) but to impossible conclusions for tissue in anaerobic conditions. Thus, respiring slices at 37° C. would need about 6 per cent of the potentially available metabolic energy for the steady-state exchanges of sodium and potassium. Anaerobically the Q_{CO_2} (μ l./mgm. dry wt./hr.) was +2.3 at 37° C. and less than +0.1 at 0° C. The exchange-rates (μ moles/mgm. dry wt./hr.) between the intra- and extra-cellular fluids at the two temperatures were 3.6 and 3.1 for sodium and 0.9 and 0.5 for potassium respectively. The potassium concentration in the tissue was about five times that in the medium, and a similar ratio for sodium was about 0.6 at both temperatures. Even on the assumption that the whole of the carbon dioxide evolved was associated with reactions yielding the same energy as those in lactic acid production from glucose (cf. Bernstein²) these results mean that, on the basis of this method of calculation, the energy requirements for steady-state exchanges of sodium and potassium at 37° C. and 0° C. would be 180 per cent and 2,500 per cent respectively of that which is available. It is of interest that the rate of exchange of potassium between 'Zeo-Karb 225' (10–30 mesh) and 0.01 N potassium chloride in equilibrium with it was found to be 10–25 times greater than the rates in kidney slices, though, of course, no energy was supplied.

These results show that it is not possible to calculate energy requirements for steady-state exchanges of ions from kinetic and thermodynamic data without information on the mechanisms responsible for the exchange.

Vibrations as a Cause of Disintegration in Liquid Sheets

DURING photographic investigations into the disintegration of liquids by means of single-fluid pressure-atomizers, it was established that the liquid first forms a thin sheet which disintegrates well away from the mouth of the nozzle. The modes of disintegration of these sheets are influenced by the properties of the liquid, the nozzle, and the surrounding atmosphere. In certain circumstances, holes are formed in the sheet which are observed to expand rapidly as they travel away from the nozzle. This process is illustrated by a high-speed photograph of a sheet of mercury as it leaves a single-hole fan-spray nozzle (Fig. 1).

It has been established that holes in the sheet can be caused by the presence of non-wettable particles in the liquid or by certain turbulence characteristics in the nozzle, as expressed by an appropriate Reynolds's number. Investigations into the latter cause reveal a phenomenon which may give a clue to the flow mechanism in all types of nozzles traversed by compressible or incompressible fluids. Vibrations which give rise to the noise phenomenon in gaseous jets are thought to be set up by the flow of the gases through the nozzle. These periodic disturbances have for some time been the subject of observation, experiment and mathematical analysis. With liquid jets there is much evidence of turbulent, unsteady flow behind the nozzle being a primary cause of disintegration, but no experimental confirmation of periodic vibrations in liquid jets has yet been forthcoming.

Observations on sheets of liquid such as the above show random centres of disturbance which, as they travel away from the nozzle mouth, eventually break the film and result in holes. Fig. 2 shows a section of a sheet of mercury illuminated obliquely to disclose the disturbances on its surface.

A mathematical analysis of these random disturbances shows that their origin is inside the nozzle

Fig. 2

just behind the mouth, and that the frequency of the observed ripples in the sheet is of the order of 10 kc/s. Systematic work may reveal the cause of these disturbances and link them to possible vibrational phenomena inside the nozzle.

High-Voltage Arcs in Argon-Nitrogen Mixtures

It has been known for some time that unusual discharges can be maintained in the gaseous filling (argon-nitrogen, 99.5 per cent, 0.5 per cent at about 600 mm. pressure) of commercial incandescent lamps¹. Recent studies of high-voltage arcs (1,000–2,000 V., 0–50 mamp., 60 c/s.) struck in the gaseous filling between the filament support leads of such lamps have been reported². When running the arc at low currents (0–5 mamp.), it appeared as a yellow-brown 'flame-like' glow, which had a distinct life-time of luminosity of the order of 1 sec. after the power had been switched off. As previously reported, the spectrum of this glow, photographed on Kodak I-N plates between 3500 and 9000 Å., showed only the following bands:

N₂ First positive system: (1,0), (2,1), (3,0), (3,1), (3,2) [(4,2), (5,3), faint]
N₂ Second positive system: (0,1), (0,2), (0,3), (0,4), (1,3), (1,4), (1,5)

This communication directs attention to probable excitation mechanisms involving vibrational levels of the $X^1\Sigma^+$ state of N₂, which now seem superior to those discussed previously³ in the explanation of this unusually low vibrational excitation of the $O^3\Pi_u$ and $B^3\Pi_g$ states of N₂ exhibited in this source.

The combined phenomena of unusually low vibrational excitation of the $O^3\Pi_u$ and $B^3\Pi_g$ states, and

Fig. 1

of an afterglow life-time of about 1 sec., strongly suggest that energy exchanges involving atoms and molecules in metastable states are taking place in the source. The available metastable states are: nitrogen, $\alpha^1\Pi^+$, $\alpha^1\Sigma^+$, ω , $A^1\Sigma^+$, $X^1\Sigma^+$ ($v > 0$); argon, ^3P . The vibrational levels of the ground-state $X^1\Sigma^+$ of N_2 , populated by emission of the Lyman-Birge-Hopfield and Birge-Hopfield systems, are metastable towards a radiative transition of electric dipole type to lower vibrational levels of the same state, as such transitions are 'forbidden' by a selection rule, N_2 being homonuclear. Thus nitrogen molecules in vibrationally excited levels of $X^1\Sigma^+$ have unusually long lives which will be terminated only by such processes as collision deactivation at the wall.

In the thermionically supported discharge plasma, some direct excitation of all atomic and molecular levels will be expected, but excitation of the singlet states of N_2 may be expected to predominate³. Subsequent radiation of the Birge-Hopfield and Lyman-Birge-Hopfield levels will, as explained above, cause levels of $X^1\Sigma^+$ to become populated up to $v = 26$.⁴ Recently computed values of vibrational transition probabilities of the Lyman-Birge-Hopfield system⁵ shows that levels $v = 2, 3, 4, 5$ of the $X^1\Sigma^+$ state will be populated preferentially in this way.

While the collision phenomenon (1)

cannot be disregarded as a possible way in which the $B^3\Pi_g$ levels become populated, it seems reasonable to suppose that the reactions (2)

would also be probable in view of the close energy equalities exhibited throughout, and because of the long lives and expected abundances of the reactants on the left-hand sides of (2). Subsequent radiation of the (0,0), (1,0), (2,1), (2,0), (3,2), (3,1) bands of the first positive system is then predicted from recent computations of vibrational transition probabilities of this system⁶.

The preferential population of the $v = 0, 1$ levels of the $O^3\Pi_u$ state may be similarly explained in terms of mechanism (3):

The second alternative would occur if sufficient energy were available to excite levels of $O^3\Pi_u$ higher than $v = 1$. The metastable argon atoms taking part in the collision would then be preferentially excited. The observed bands of the second positive system (0,1), (0,2), (0,3), (0,4), (1,3), (1,4), (1,5) are those which would be predicted as most probably arising from the $v = 0, 1$ levels of the $O^3\Pi_u$ state from recent values of the vibrational transition probabilities of this system⁶.

Experimental work on these discharges is continuing.

This work has been carried out as part of a project supported by the Geophysics Research Division of the U.S. Air Force under Contract No. AF 19(122)-470.

Transmission of Electrons and Holes Across a Twin Boundary in Germanium

THE recently developed technique¹ of investigating the diffusion of minority carriers in an ambipolar semiconductor has been applied to the study of a twin boundary in germanium. Twinning about a (111) plane readily occurs in crystals having the diamond structure, such as germanium and silicon. A single crystal of n -type germanium, containing one twin boundary, was pulled from the melt by the Czochralski technique. The material used was of reasonably high purity, approximately 5 ohm-cm. resistivity at room temperature. A slice approximately 0.5 mm. thick was cut from this in such a manner that the twinning plane was perpendicular to the surface, which was then ground in the usual manner and etched in $CP.4$ ². The specimen was irradiated with a narrow beam (0.05 mm. wide) of chopped infra-red light, having a wave-length comparable with the width of the forbidden energy gap, 0.72 eV. A probe close to the illuminated spot picks up an electrical signal which corresponds to the change in the Fermi-level or the floating potential under the probe. This change in the potential is proportional to the local density of minority carriers excited across the energy gap by the absorption of the radiation. The drop in signal strength observed as the light spot is gradually moved away from the probe is due to the decay in the number of these carriers. In a single crystal, such decay is caused mainly by recombination of the excess carriers at trapping centres, and a logarithmic plot of signal strength versus distance should give a straight line, the slope of which determines the diffusion distance, closely related to carrier mobility and life-time.

If the texture is not perfect, a discontinuity in signal strength would be expected wherever the electrons meet some major defect in the structure, which would result in the setting up of a potential barrier. The measurements on the specimen described, which was apparently perfect apart from the twin boundary, are plotted in the accompanying figure; they show no discontinuity, the lines being in fact quite straight and of identical slope on either side of the probe, which was located 1.1 mm. away from the boundary. Apparently, electrons passed across this boundary just as freely as they moved in the crystal where they originated.³

The diffusion distances derived from these measurements are given below, together with the corresponding life-times, calculated on the assumption of $43 \text{ cm}^2 \text{ sec}^{-1}$ for the diffusion coefficient of holes. The somewhat lower value for 1.5μ is presumably due to the increased absorption of the radiation near the surface layer and the correspondingly higher rate of recombination there.

Wave-length (μ)	1.5	1.7	1.8	1.9
Diffusion distance (mm.)	0.54	0.63	0.66	0.66
Life-time (sec.)	68	92	98	103

As a further check on the transmission of holes across a twin boundary, transistor action was investigated on another similar crystal with an emitter point on one side of the twin boundary and a collector on the other. The two points were spaced about 0.2 mm. from either side of the boundary. Distinct transistor action was observed as readily as on any similar piece of single-crystal material.

It would therefore appear that, in contradistinction to grain boundaries, twin boundaries will not impede the transmission of free electrons or holes to any marked degree. This is not surprising, as the transmission from one twin to the other takes place across a single atomic layer; also, the energy involved in twinning is quite negligible compared with the main lattice energy. Electrons and holes can obviously bridge such a narrow region by the wave mechanical tunnel effect without any marked resistance.

It is suggested that similar techniques might, with advantage, be applied to the study of various faults

in the structure of solids, as, for example, to the boundary region between two grains which have been made to grow with certain specified orientations.

Fatigue Strength of Pure Tin at Room Temperature

THE fatigue strengths of many tin alloys at both room and elevated temperatures have been reported¹, but I have found no figure for pure tin in the literature. Experiments have therefore been made to determine the fatigue strength of the pure metal in the cast condition. The measurements were made on a Wohler type machine with four-point loading, using a relatively thick specimen with a short gauge-length.

Tests were made up to 10^8 cycles of stress and these showed no evidence of a true fatigue limit. The fatigue strengths at 10^7 and 10^8 cycles of stress are 0.19 and 0.17 ton per square inch respectively.

It is of interest that the fractures produced by fatigue were wholly intercrystalline. After testing, the grain boundaries were revealed on the polished surface of the specimen, indicating that intergranular movement had taken place during the test. In addition, a general roughening of some grains indicated that transcrystalline deformation occurred at the same time, either on sub-boundaries or on slip planes.

Graphite Lubrication in Grey Cast Iron

DURING work with the Lunn apparatus¹ on dry friction between a sliding tungsten carbide ball and a grey cast iron test-piece, two different types of tracks were obtained. The first type of track had a black appearance when examined with the naked eye or in the microscope, and a continuous film of deformed graphite covered the surface of the track. The L value of this film was high, which indicated good electric conductivity of the film. The second type of track had a bright, metallic appearance, and on examination with the microscope very small amounts of deformed graphite were observed. In this case, the L value was low, which indicated the build-up of an insulating film—even if the specific pressure is of the magnitude of $10,000\text{--}12,000 \text{ lb./sq. in.}$

The two types of tracks could be produced on the same test-piece, depending on the conditions under which the experiment was carried out. If conditions did not allow water vapour to be adsorbed to the cast iron surface, the first type of track was obtained. Adsorption of water vapour always resulted in a change to the second type of track.

These observations made on grey cast iron are in agreement with the experiments of Savage¹ on the lubricating effects of pure graphite.

Very Long Sequences of Geomagnetic Activity and Its Annual Variation

It is well known that moderate geomagnetic storms tend to recur after 27 days. Such storms are not related to sunspots, are almost always of gradual commencement type and are well marked only during two or three years immediately preceding the sunspot minima. A large number of such sequences, consisting of seven or eight storms, have been recorded; a few much longer sequences have been mentioned by Bartels¹. The longest sequence of which we are aware in the literature consisted of seventeen recurrences between December 9, 1929, and March 13, 1931.

We have studied the recurrence tendency of geomagnetic activity for the three-year period 1950-53. A plot of three-day running means of the international magnetic character figures *C* for this period indicates that sequences of magnetic activity last much longer than has been thought hitherto. Our study further indicates that, after exhibiting well-marked storm-like characteristics for about five to six recurrences, the activity diminishes to such proportions that it can no longer be identified with a storm. Very often this may be regarded as the end of a sequence. We find, however, that the activity, after remaining low for a few recurrences, again becomes appreciable and the continuity of the sequence is maintained.

During the three-year period under consideration two long sequences have been identified. These sequences will be called *A* and *B* respectively. In addition, there are a few short sequences corresponding to two or more 27-day rotations and a few individual peaks of considerable activity, the latter mostly associated with sudden commencement type of storms. The major part of the activity, however, is covered by the *A* and *B* sequences.

The *A* sequence which commenced with the moderate storm of July 11-12, 1950, has continued to date; the latest storm of this sequence as recorded at Kodaikanal commenced on September 19, 1953. The *B* sequence appears to have begun on November 21, 1951, and has also continued to date, the latest storm in the sequence having started on September 3, 1953. The total number of recurrences of the *A* sequence so far is 40, and that of the *B* sequence 21. Most of the time the magnetic activity for both the sequences has been pronounced after 27 days, but in a few cases the period between individual days of highest activity was 26 or 28, and only in a very few cases 25 or 29. The mean period between recurrences for each one of the sequences is found to be 27.05 days.

The activity on individual days when it was maximum during the recurrences has been plotted for the two sequences using the actual *C*-figures for the days concerned. The curves show a regular periodicity;

the activity associated with the *A* sequence shows maxima only once a year about September-October and minima about March-April, whereas for the *B* sequence the yearly maxima occur about March-April and minima about September-October. The yearly maximum of activity rather than six-monthly maximum (equinoctial) appears to throw some light on the causes of seasonal variation of magnetic activity. It has been known for a long time that the mean monthly geomagnetic activity shows maxima about March and September—months of vernal and autumnal equinoxes. Bartels¹, who studied the annual variation of geomagnetic activity for a period of fifty-nine years, 1872-1930, found equinoctial maxima of activity to exist for years of high and medium as well as low sunspot activity. However, since monthly means of all geomagnetic activity were used by him, it was not possible to say whether, corresponding to each individual *M*-region, the variation of geomagnetic activity had a six-monthly period or whether the period was twelve months, with some *M*-regions giving rise to maximum activity about March and others about September. From his harmonic dial method, Bartels concluded that only the semi-annual wave of geomagnetic activity was physically significant. The sequences *A* and *B* which, in our opinion, are associated with two *M*-regions, show a behaviour quite contradictory to the idea of semi-annual wave. This result could not have been conclusively obtained without the identification of very long sequences.

The heliographic latitude of the earth attains its maximum positive and negative values of 7.2° on September 7 and March 5 respectively. If we postulate that the intrinsic activity of an *M*-region responsible for geomagnetic activity remains nearly constant over a period of the order of a year, the following conclusions can be drawn from the geometry of the situation. (a) If an *M*-region is located at heliographic latitude greater than 7.2° north or south, there will be a single maximum of geomagnetic activity centred around September 7 or March 5, depending upon whether the *M*-region is in the northern or the southern solar hemisphere respectively, with the minimum occurring on the other date. (b) If the heliographic latitude of the *M*-region is less than 7.2° north or south, there will be two maxima of activity situated more or less symmetrically about September 7 or March 5, depending upon the hemisphere (north or south) in which the *M*-region is located. The displacement from these dates will depend upon the latitude of the *M*-region. (c) If the *M*-region is located on the solar equator, there will be two maxima, about December 8 and June 6.

From our study of the recurrent storms during the period 1950-53 we may conclude that:

(1) There were two principal long-lived *M*-regions separated in longitude by about 180° . These were responsible for two separate long series of magnetic storms.

(2) A single yearly maximum for each of the series indicates that these *M*-regions were located at heliographic latitudes greater than 7.2° . The mean period of recurrent geomagnetic activity of 27.05 days indicates their position at 7.5° heliographic latitude if judged from synodic rotation period of sunspots and 16° if considered from that of prominences.

(3) The characteristic annual variation of geomagnetic activity, which was mainly associated with solar *M*-regions during the three-year period considered here, is found to be due to the approach of the earth's projection on the solar disk towards the

zones of maximum solar activity. Incidentally, this explanation of the annual variation is in accord with that given by Cortie² from his studies of the geomagnetic activity associated with sunspots.

Details of the investigation reported here will be published elsewhere.

Size of Fragments resulting from Tidal Disintegration

THE size of tidal fragments of a body composed of rock or ice, according to Jeffreys¹, would exceed 200 km. Since primary tidal stresses are tensile, they would elongate the disrupted body in the direction toward the other body, thus producing a long axis in this direction and tearing the disrupted body into disks the thickness of which might be, as Jeffreys suggests, more than 200 km.

The effect of secondary tidal stresses is not included in Jeffreys's computations and, therefore, his conclusions are questionable for large bodies. Within Roche's limit, the gravity holding the body together is neutralized only in the direction of the long axis, but is unaffected at right angles thereto. That is, the pressure on the materials varies from zero at both ends of the long axis to approximately its original value midway between. In the central disks, the secondary stresses due to the weight of the material must be considered in addition to the tidal tension tearing the body apart. Other secondary stresses due to change in direction of primary tidal stresses are minor, and are not discussed.

For example, consider that a body of the size and density of the earth is being disrupted by a tidal encounter, and that its surface rocks have a density of 3 gm./cm.³ with an ultimate crushing strength of 2,000 kgm./cm.². In the central disks the ultimate crushing strength of the rock would be reached at a depth of 6.7 km. below the surface. Below this level the rocks would fail by compression and shear, the materials of the disks would bulge into the widening rifts, and spalls and other fragments would fall into these rifts. Meanwhile, fragments less than a kilometre in size from above the 6.7-km. level would be broken off by tension, for the tensile strength of rock is less than 0.1 its compressive strength. Wherever the compression stresses exceed the ultimate strength of the rock, much of the rock would be crushed into small pieces, of which many would be as small as sand. Pieces falling into the rifts would be broken by impact.

Thus it seems possible that the combination of primary tidal tension and secondary stresses of compression, shear and tension would be competent to produce fragments much smaller than the 200-km. minimum computed by Jeffreys.

In the case of tidal disruption of smaller bodies, the size of fragments would vary approximately inversely as their acceleration of gravity; but even if the disrupted body were only a few hundred kilo-

metres in diameter, it would still be possible that secondary stresses would produce many small fragments.

Processes controlling Zygomorph Formation and Zygotropism in *Mucor mucedo* Brefeld

ASPECTS of the process of conjugation in *Mucoraceae* have recently been discussed by Raper¹, Goodwin², Hawker³ and Catcheside⁴. In view of current interest in sexual processes in the *Thallophytes* the following incomplete results are presented.

Burgeff⁵ believed that zygomorph formation in *Mucor mucedo* was sometimes induced by an air-borne volatile substance or substances; he and Köhler⁶ also produced evidence for a water-soluble hormone which acted similarly after diffusing through the substrate. I have grown strains of *M. mucedo* from Basen (showing no spontaneous zygomorph formation) in a closed-ring system through which air was constantly recirculated while slowly exchanging with the outside atmosphere. Colonies, (+) and (−) in an alternating linear series on small separate blocks of agar, did not form zygomorphs when separated by 3-mm. air gaps; when they were separated only by sheets of permeable 'Celloidin' (which remained unpenetrated by hyphae) zygomorphs arose in the contact zones. There does not appear to be any strong evidence for air-borne induction of zygomorph formation. Several workers have obtained evidence for the existence of diffusing hormones in the substrate, but no active extract or metabolite fluid has been isolated.

Two methods have given inconclusive but promising results. In the first, liquid decanted from mixed (+) and (−) mycelia growing submerged in aerated 2 per cent malt extract solution, filtered, and concentrated by partial freezing and removal of ice, was tested by transferring to antibiotic assay cups placed about 3 mm. from the growing edge of (+) and (−) colonies. Occasionally in repeated tests local production of zygomorphs was observed in the (+) but not in the (−) colony. Malt solution alone treated as above had no effect. Recently, using a modification of Raper's cascade technique, distinct zygomorph formation (with no signs of copulation) was observed when 2 per cent malt extract solution having previously passed through (+) and then (−) mycelia reached a second (+) culture. This unfortunately gives no clear indication of the sequence of hormone production, but it is hoped that current work will provide an unequivocal answer on this point.

The next stage in the conjugation process, the zygotropic response, was studied using small blocks of agar cut transversely from the copulation zone between (+) and (−) colonies newly grown into contact in Petri dishes. There was thus a tuft of unmixed (+) zygomorphs at one end of the block, a mixed tangle with copulation in the middle, and (−) zygomorphs at the other end. Successive series of these blocks were then arranged by hand or micromanipulator so that zygomorphs of one type were brought near those of either the same or alternatively the opposite mating type, pointing in various directions, and at various distances. Repeated observations confirmed

the mutual positive response between (+) and (-) xygophores. Further, a mutual aversion between xygophores of the same mating type was discovered; that is, (+) xygophores are repelled by (+), and (-) by (-). The attraction has been detected over a distance of 2 mm., the repulsion over 1 mm. Neither effect was shown when the xygophores on one side of the gap were replaced by vegetative mycelium of either mating type bearing sporangiophores but no xygophores.

Vandendries and Brodie (see Buller⁷, and Langeron⁸) claimed that the repulsion, over distances of up to 3.5 mm., which they observed between certain haplonts of *Leontia betulina* was transmitted through thin air-tight barriers of glass, mica, celluloid and silver, and must be due not to a chemical stimulus but to radiations. I was unaware, until recently informed by Dr. J. H. Burnett, that this claim was later withdrawn by Vandendries⁹ in a little-known paper. In my experiments, when thin barriers (2-50 mgm./cm.²) of fused quartz, glass, mica or aluminium foil were erected between paired tufts of xygophores prepared as above, no attraction or repulsion was observed, nor was it when normal diffusion between xygophores was interrupted by a current of moist air from a micro-jet. Using mica or aluminium foil with a fine perforation as a barrier, attraction was manifested, (+) and (-) xygophores respectively curving from opposite sides and growing towards the pore even when the arrangement was such that no straight path existed between any xygophore on one side through the hole to one on the other side. These results indicate that xygotropism in *M. mucedo* is a form of chemotropism and not, as suggested by Köhler, a response to any electromagnetic radiation. It seems necessary to postulate two volatile substances, one evolved by (+) xygophores, stimulating elongation growth in (+) xygophores and retarding it in (-) xygophores, the other evolved by (-), stimulating (-) and retarding (+). A directional response could occur, since the frequency with which diffusing molecules of the active substance impinge on the near face of the xygophore is greater than on the side away from the source: estimates of the difference suggest values of the order of 0.1-0.5 per cent. This is of the same order as the estimated minimum difference in light-energy absorption required for phototropic curvature of *Phycomyces* sporangiophores under unequal bilateral illumination¹⁰, so a xygotropic curvature from such a minute difference is quite conceivable.

A more extensive account of these and other observations, with appropriate acknowledgments, is being submitted for publication in the *Journal of Experimental Botany*.

Nematode-destroying Fungi In Agricultural Soils

IN view of the serious losses to crops caused by eelworms, and the possibility that their destruction by predacious fungi may be of potential value as a means of control, some knowledge of the natural occurrence of these fungi in arable soil is desirable. The results set out below are those of a survey carried out on forty-nine samples of soil from various parts of England. The samples were taken from arable land, much of which was infested with potato root eelworm or cereal root eelworm, and from glass-houses in Warwickshire in which tomatoes were the principal crop, and in many of which the potato root eelworm was causing damage.

For examination of the samples, a little soil was scattered on the bottoms of sterile Petri dishes, and maize-meal agar, cooled to about 40° C., was poured into the plates, the soil being slightly mixed with the agar by gentle tilting. The medium was approximately neutral in reaction, no adjustment of pH having been made. The plates were incubated at room temperature, and periodically examined for predacious fungi. In order to keep down the growth of moulds, a very weak infusion of maize-meal was used in making up the medium. Predacious fungi usually began to appear in about a fortnight after inoculation, feeding on the free-living eelworms that wandered out on to and into the agar. Each batch of plates was kept under observation for a minimum period of three months.

From the forty-nine samples that were examined, eighty-two records of nematode-attacking fungi were made, a list of which is given below; the numeral following the name of the fungus represents the number of samples in which it was found.

<i>Arthrobotrys dactyloides</i> Drechsler	4
<i>A. oligospora</i> Frey	21
<i>A. robusta</i> Duddington	2
<i>Arthrobotrys</i> spp.	2
<i>Dactyloctenium aegyptium</i> (Koe) Sacc.	2
<i>D. psychrophilum</i> Drechsler	-1
<i>Dactyloctenium bembicoides</i> Drechsler	1
<i>D. cocciniforme</i> Drechsler	1
<i>D. lobata</i> Duddington	1
<i>Dactyloctenium</i> or <i>Dactyloctenium</i> spp.	2
<i>Trichothecium mycelium</i> Duddington	3
<i>Acrostalagmus obovatus</i> Drechsler	5
* <i>Acrostalagmus</i> sp. 282, n.sp.	1
* <i>Haptoglossa heterospora</i> Drechsler	6
<i>Haptoglossa angulata</i> Lohde	1
<i>H. klugiana</i> Dixon	1
<i>Maria concolor</i> Drechsler	1
* <i>Nematotomus heterospora</i> Drechsler	2
* <i>N. pachysporus</i> Drechsler	1
<i>Mycelium</i> 186	18
Undescribed hyphomycetes	6
Total number of records	82
* First British record	

The fungus referred to as 'Mycelium 186' is very common in soil. It is clearly a member of the Zoopagaceae, having non-septate hyphae that capture nematodes by simple adhesion, no specialized organs of capture being formed. No reproductive bodies of any kind have been observed, nor has the fungus ever appeared in any other habitat save soil. A full description of this fungus will be published elsewhere. *Acrostalagmus* 282 is a hitherto undescribed species with clavate spores; it is here placed for convenience in *Acrostalagmus* Corda (*conu* Drechsler), but may ultimately have to be described as the type of a new genus, owing to the unsatisfactory taxonomic status of *Acrostalagmus*. The interesting fungus *Haptoglossa heterospora*, probably best placed in the Lagenidiales, has already been found in soil in Denmark by Shepherd (*in litt.*).

A consideration of the list brings out one or two interesting points. The commonest fungus is *Arthrobotrys oligospora* (21 records), which is not surprising in view of its widespread distribution in many kinds of habitat¹. Its great preponderance over all other species except 'Mycoelium 186' is, however, surprising. Easily the second commonest is 'Mycoelium 186' (18 records); as this fungus has been recorded only from soil, it would seem likely that it is a specialized soil species, and it is possible that its constant failure to produce spores when grown on agar media may be correlated with this. How it reproduces in its natural habitat is not known, but among other factors the disruption of soil by earthworms might perhaps be considered. Like *Arthrobotrys oligospora*, it outnumbers other fungi in the list to a surprising extent. *Arthrobotrys dactyloides*, capturing eelworms by means of constricting rings, appears to be more frequent in soil than elsewhere. It has been obtained in Great Britain from compost by Dixon (personal communication), but apart from its occurrence in soil it does not appear to be a common British species. It has also been observed in Danish soil by Shepherd (*in litt.*). *Trichothecium cystosporium* is fairly prominent, and this species has also been isolated from soil on a previous occasion². The other species in the list call for no particular comment, though the frequencies of the ubiquitous *Harposporium anguillulae* and *Acrostalagmus obovatus* may be noted. The preponderance of hyphomycetes capturing nematodes by means of adhesive networks is also interesting.

Attempts to correlate the presence or absence of particular fungi with soil factors such as pH, etc., yielded no results; but it is clear that many more soil samples will have to be examined before any such correlations, if present, can be expected to become apparent. Quantitative information on the distribution of predaceous fungi in soil is also badly needed; this work is now in hand, and it is hoped to make it the subject of a future communication.

I should like to express my thanks to Mr. F. G. W. Jones, School of Agriculture, Cambridge; to Mr. H. C. F. Newton, Miss O. M. G. Duthoit and Mr. H. J. Ward, of the National Agricultural Advisory Service, West Midland Province; and to Mr. M. Brook, of Boots Pure Drug Co., for their help in providing many of the soil samples on which this preliminary survey has been based. The work has been made possible by a grant from the Agricultural Research Council, to which my thanks are also due.

Demonstration of a Diffusible Fruiting Factor in Myxobacteria

RUNYON¹ gave a demonstration of a diffusible factor inducing the formation of fruiting bodies in Myxamoebae. Attempts to demonstrate a similar factor in *Chondromyces* by Bonner² are inconclusive because they resulted in mechanical disturbance of the swarm and of the surface of the medium, which are sufficient, in my experience, to stimulate the formation of fruiting bodies (cf. also Stanier³).

A very striking demonstration of such a factor in myxobacteria was obtained by placing squares, about 2 cm. × 2 cm. × 4 mm., of non-nutrient agar over fruiting bodies of one strain of *Chondromyces axiginus* and two of *Myxococcus xanthus* grown on a killed suspension of *Aerobacter aerogenes* in non-nutrient agar. The upper surface of these agar squares was inoculated with suspensions of vegetative cells, grown on one-tenth strength routine nutrient agar, which supports their growth but does not permit formation of fruiting bodies. Great care was taken to avoid mechanical disturbance of the agar surface; and as controls similar inoculated squares were placed on uninoculated *A. aerogenes* suspension plates, and some squares covering fruiting bodies were left uninoculated.

After three days incubation at 28°C., profuse formation of fruiting bodies occurred in the vegetative cells placed over fruiting bodies of the same species, but not in the controls, or in those vegetative cells of *M. xanthus* which were placed over fruiting bodies of *Ch. axiginus* or vice versa. The two strains of *M. xanthus* were mutually stimulatory.

Fruiting bodies did not form immediately over those below, but were most profuse at the edges of the inoculum, that is, at the greatest concentration of vegetative cells. This appears to indicate that the factor is rapidly diffusible. Further, increased formation of fruiting bodies in the areas covered by the agar was found to occur both with inoculated and uninoculated squares, and was apparently due to the mere presence of the agar.

It has been suggested by Quahl⁴ that compatibility, as indicated by the coalescence of vegetative swarms in close proximity, might be employed as a means of definition of species in myxobacteria. However, it is my experience that otherwise identical swarms may fail to coalesce, and it may be that the mutual stimulus of the formation of fruiting bodies could be employed for species or type differentiation.

Delay of Chromosome Rejoining in *Vicia faba* Induced by Irradiation

I HAVE shown¹ that fractionation of X-ray dosage administered to seeds of *Vicia faba* soaked in water causes no decrease in the number of two-hit chromosomal aberrations. However, with additional soaking in the protective agent, 2,3-dimercapto-propanol (BAL), previous to irradiation, a decrease is achieved on dosage fractionation. In order to further the understanding of this phenomenon, the following dosage-intensity experiments were performed. A constant dosage of 600 r. of 250 kVp. X-rays was administered in 3-min., 1-hr., 2-hr. and 3-hr. periods. The numbers of ring and dicentric chromosomes in 300 metaphase plates of the X-1 root-tip division were scored at each intensity.

As can be seen from Fig. 1, in those seeds soaked in water alone, there is no significant difference in the number of aberrations produced by the highest

Fig. 1. Effect of intensity on chromosome aberrations. Upper curve, seeds soaked in water; lower curve, seeds soaked in 2,3-dimercapto-propanol

three intensities. Only when the dose is administered over a greater period of time than 2 hr. is there a decrease in the number of aberrations. This is easily explained if one assumes that no rejoining of broken chromosome ends occur within 2 hr. of the onset of radiation. However, if the seeds are pre-soaked for 1 hr. in a solution of $2 \times 10^{-3} M$ 2,3-dimercapto-propanol, there is a significant decrease in the number of two-hit aberrations as the intensity is decreased; evidently the 2-hr. lag period, during which little or no rejoining normally occurs, has been decreased. This effect of 2,3-dimercapto-propanol, a powerful antioxidant, strengthens the hypothesis that the major effect of apoxia is on the restitution of broken chromosomes^{1,2} rather than on the initial breakage³.

That the rings and dicentrics scored are authentic two-hit aberrations may be ascertained from the dosage curve in Fig. 2, which shows that the numbers of these aberrations increase as the square of the dose. This is contrary to previously published dosage curves⁴ on two-hit chromosome aberrations in the

Fig. 2. Dosage curve of two-hit chromosome aberrations. Intensity, 200 r./mm. Dotted lines enclose 96 per cent confidence limits

seed of *Vicia faba*. This discrepancy is probably due to the fact that a large proportion of the anaphase bridges scored by others⁴ as two-hit aberrations are in reality the result of one-hit isochromatids.

This work was carried out under Contract No. 7405-eng-26 for the Atomic Energy Commission.

Hydrostatic Pressure-Deficiency and the Emergence of Larvae from Cysts of the Beet Elworm

LARVAE of the beet elworm (*Heterodera schachtii* Schmidt) are essentially water-inhabiting creatures, and their behaviour in the soil is governed by the properties of the soil water. The results of an investigation into the relationship between hydrostatic pressure-deficiency in an artificial soil composed of sand and water, and the number of larvae emerging from the elworm cysts, are summarized here.

One hundred cysts, mixed in 9 gm. of sand of particle-size 60–160 μ , were placed in each of a series of sintered glass funnels. Suction was then applied to the sand and water in each funnel to give a range of pressure-deficiencies. The apparatus was kept in a constant-temperature room at 24°C. ($\pm 0.5^\circ C$). The relationship between the logarithm of the pressure-deficiency (pF) and the numbers of larvae emerging is shown in Fig. 1.

A comparison of the curve for the moisture characteristic (that is, the curve of moisture content plotted against the logarithm of pressure-deficiency) with the curve for larval emergence and the logarithm of pressure-deficiency shows that a relatively low emergence occurs with 1–10 cm. pressure-deficiency when the sand is saturated. Maximum emergence corresponds to the pressure-deficiency at which the last pore space is emptied of water.

Other experiments have shown that larval emergence is dependent on oxygen concentration; at low oxygen concentrations (1–2 mgm. of oxygen per litre)

emergence is almost nil. It is suggested that the relatively low emergence occurring during 1-10 cm. pressure-deficiency is due to low oxygen concentration in the water around the cysts when the sand is saturated and the pore spaces are filled with water. An increase in emergence occurs after 10 cm. pressure-deficiency, when air appears in the pore spaces, resulting in increased oxygenation of the water film. Emergence rises to a maximum at 70 cm. pressure-deficiency, after which there is a decline. Two possible explanations of this decline are suggested. Egg hatch may be inhibited by the extraction of water from the cysts, and larval emergence may be impeded by the surface forces of the water film.

The effects of oxygen concentration, temperature, saturation deficiency, size of soil particles and different soil types on larval emergence are also being investigated.

I am indebted to the Sugar Beet Research and Education Committee for providing facilities for carrying out this investigation.

Hardness of Arthropod Mouthparts

It is well known that many insects are able to bore through packing materials, including metal foils, used for wrapping foodstuffs and other commodities. During an attempt to develop a physical barrier that would be resistant to penetration by insects, the hardness of the mouthparts of a number of insect pests was determined.

Richards¹ considers the question of the hardness of arthropod cuticle, but it appears that no determinations have been made. In view of this, representatives of several insect orders and of other classes of arthropods were included in these tests.

Fresh materials were used in each case and the mouthparts, generally the mandibles, were removed and cemented to needles. Scratch tests were carried out on the minerals in Moh's scale of mineral hardness (see Lange²) which would appear to be the appropriate standard.

Determinations were made on species of the following genera:

Insecta
Coleoptera: *Tenebrioides*, *Rhizopertha*, *Stagobium*
Lepidoptera: *Pterolocusta*
Isoptera: *Mastoterms*
Orthoptera: *Calcaripr*
Crustacea
Decapoda: *Oherus*
Myriapoda
Chilopoda: *Scolopendra*
Arachnida
Scorpiones: *Carcophonus*
Arachnida: *Isope*

In each case the hardness was found to be approximately 3, the specimen of calcite being scratched with difficulty. Minerals softer than 3 were readily marked. In view of the function of mouthparts, this may represent the highest value to which arthropod cuticle can be hardened.

It is of interest to consider the role taken by calcification of the cuticle which occurs notably in the Crustacea. Many authors have examined the calcium salts involved, and it appears that calcium carbonate in the form of calcite is the usual deposit. Whatever properties calcification may modify, it is

clear from the present results that it will neither harden nor soften the cuticle.

From the above evidence there would appear to be no physical difficulty in insects boring through foils made from such common metals as lead, tin, copper, zinc and silver, providing that these have not been work-hardened.

I am indebted to Mr. A. Musgrave, of the Australian Museum, for identification of the Arachnida.

Effect of Refrigeration of the Pupae of *Microbracon brevicornis* Wesm. on the Pigmentation of the Adult

DURING the course of mass breeding of *Microbracon brevicornis* in the parasite laboratory of the Entomology Division of this Institute for the purpose of exporting them to the United States of America for the control of pink boll worm in the cotton belt of that country, it was necessary to maintain a stock of pupae of the parasite in cold storage at a temperature of $10 \pm 3^\circ \text{C}$. It was observed that the adults emerging from the chilled pupae which had been in cold storage from 10 to 75 days showed dark pigmentation ranging from dark grey to jet black, as against the distinctly brown individuals obtained from unchilled pupae.

The possible effect of humidity on the production of melanic forms was eliminated by subjecting the pupae to low ($10 \pm 3^\circ \text{C}$.) and high (25°C .) temperatures at different humidities. Irrespective of the humidity, the parasites that underwent metamorphosis under low temperature always showed darker pigmentation. Similarly, the effect of light on the pigmentation of the adults also showed that while dark forms emerged from chilled pupae, whether kept in darkness or in light, all adults that were obtained from pupae at higher temperatures under both conditions were brown individuals. It was thus concluded that low temperature alone was responsible for the abnormal pigmentation of adults obtained from the chilled pupae.

Kaestner¹ observed that when females of *Habrobracon* are exposed to extremes of heat or cold, the parasites became dark and the effect was transmitted apparently through the plasma to the next generation. However, in the present case it has been observed that the dark forms when bred at a temperature of 25°C . and 70 per cent humidity gave rise to normal brown individuals. Evidently in this case the progeny has failed to inherit the acquired character of their parents, and we are therefore unable to confirm Kaestner's observations. Genies, Schlottke and also Kuhn² have shown that, in the case of *Microbracon habitor*, at low temperatures the black pigments become dominant, whereas at higher temperatures the pigmentation is more reduced until finally entirely yellowish forms are produced. In the present case, even when the parasites were bred at 35° and 40°C ., they did not exhibit any loss of pigment-

ation. Genies and others have not connected low temperature with depressed metabolism in insects, which appears to be one of the probable causes for dark pigmentation.

The conclusion from these experiments is that pigmentation in this case is perhaps a physiological phenomenon caused by the inability of cells to dispose of the breakdown products of metabolism in chilled pupae at a low temperature; these products tend to increase and accumulate as the period of refrigeration is extended. This explanation supports the hypothesis put forward by Cordier³ that "the production of melanin is sometimes regarded as a mechanism for disposing of toxic phenols arising as breakdown products in metabolism".

Extending these findings to field-conditions, it will now be possible to explain the occurrence of seasonal forms of *M. brevicornis*. A source of confusion is the great variation in colour to which *M. brevicornis* is liable; it is evident that the difference in colour is almost valueless in defining species. The parasite over-winters in the pupal stage and therefore the adults emerging from the over-wintering pupae are dark in colour compared with the brown forms that emerge during the spring. This was confirmed by the specimens collected from cotton fields in northern India where, during the months of January and February, the field-temperature is very low. Hence it is possible that early workers in India, though they might have reared *M. brevicornis* from pink boll worm (*Platyedra gossypiella* Saunders), took it for granted that the parasite was *M. lefroyi* D. and G., and never recorded *M. brevicornis* as a potential parasite of pink boll worm.

Culture of Insect Tissues

IN recent years, in fact since the culture of vertebrate tissues became an accepted laboratory technique, insect physiologists have attempted to produce cultures of insect tissues. So far, they have not succeeded. All that has been achieved with insects is the maintenance of organs in a living state¹, sometimes with the continuation of metamorphic changes², or a limited growth of tissues still organically connected with the living body of the insect³. The literature also contains reports of insect-tissue culture which can be assigned to one of two classes: either growth has genuinely taken place during an experiment of extremely short duration⁴, or else what was probably a mere cell migration, such as I have found with *Rhodnius prolixus*, was recorded as growth⁵. The criterion of a tissue culture which is to compare with vertebrate tissue culture would seem to be the possibility of maintaining it by means of sub-cultures, over an extended period of time, and it is in this sense that previous efforts may be said to have failed.

Apart from the work of Luschar⁶, which in any event was not intended as a true *in vitro* cell culture, no attempts at tissue culture have been carried out on insects of the order Hemiptera-Heteroptera, of which *Rhodnius prolixus*, a useful and convenient laboratory insect, is a representative. It seemed to me that *R. prolixus* would be a very suitable insect for such experiments, since so much is already known about it. It has been found, for example, that the epidermis of *R. prolixus* will grow when implanted into the body cavity of another individual, whereas the other tissues degenerate⁶. The epidermis of this insect will also grow to a certain extent along glass tubes inserted into the cut ends of limbs⁷. The processes of wound repair in the living *R. prolixus* are well known⁸, and have been found to involve the proliferation of the epidermal nuclei.

In the experiments to be described here, fourth and fifth instar nymphs of *R. prolixus*, which had been fed four to seven days previously, were used. They were surface sterilized for five minutes in 0.1 per cent aqueous mercuric chloride, washed in three changes of sterile water, and then put into a sterile Petri dish lined with filter paper, where they remained until dry. Using a sterile technique, hanging drops of the insect's hemolymph were made, in which small snips of the abdominal cuticle and epidermis were suspended. Care was needed in order not to puncture the blood-laden stomach, and drops which were visibly contaminated with the stomach contents were discarded. Altogether, forty-eight sterile drops were prepared, and the proportion of losses due to bacterial infection was very small when mercuric chloride sterilization was used. Lysol (25 per cent) and methylated spirits were also tried as sterilizing agents, but had a deleterious effect on the insects, as shown by the failure of controls, sterilized but not dissected, to recover. It was found that bacterial infection was much more severe in drops made after the use of these latter sterilizing agents, and this suggests some ability of undamaged cells to cope with invading micro-organisms.

In a typical hanging drop, visible changes could be seen to occur, but unfortunately they can only be regarded as degenerative in nature. After the first twenty-four hours, a mass of vacuoles and chromatic granules flowed out from the edge of the cuticle, while the rest of the epidermis contracted towards the centre of the cuticular fragment. Hemolymph cells were numerous in the drops at first, but disappeared later. In three of the drops, there were many amoeboid hemolymph cells, which coalesced into compact groups, and remained for the duration of the experiment. Their nuclei stained apparently normally at the conclusion of the period of incubation. After 10-14 days incubation at 30° C., that is, a few days after visible changes had ceased, the preparations were fixed and stained. Many nuclei could be seen, but rather weakly stained, and no mitoses were visible.

A few trials were made with other parts of the anatomy of *R. prolixus*, such as heart, testis, muscle and fragments of unfed first instar bugs; with bacteriological broth instead of hemolymph as a medium; and with tissues of the cockroach *Blattella orientalis*. No success attended any of these variations.

There are two obvious developments of the methods here employed which occur to me and may be mentioned. The first is to replace glass surfaces by

mice, or cover them with a film of wax, and the second is, by analogy with vertebrate tissue culture, to enrich the culture medium with an extract of *R. prolixus* embryos. These developments have not been possible at present, and the brief account given here is for the benefit of those who may wish to follow this line. It is important to emphasize that, up to now, there is no indication whatever that insect tissues will form cultures of the sort familiar with vertebrate material.

Occurrence of *Puccinia polysora* Underwood in the Indian Ocean Area

THE maize rust fungus *Puccinia polysora* was first described in 1897 by Underwood in Alabama on *Tripsacum*, a plant allied to maize; it was later also found on *Eriophorum*, a species of grass related to the sugar-cane. In 1941, Cummins detected the fungus for the first time on maize in the United States, but a careful review of herbarium material collected earlier from different parts of the Continent and deposited as the common maize rust, *P. sorghi* Schw., brought out that many of the specimens had indeed been attacked by *P. polysora*.

The new rust, which does not apparently cause severe injury to maize in the New World, was until recently unknown in the Old; but in 1949 a severe outbreak of the disease was observed in Sierra Leone in West Africa. The following year, serious epidemics broke out in Liberia, Ivory Coast, Gold Coast, Dahomey, Togoland and Nigeria, resulting in food shortage among the native tribes. By the end of 1952, the disease had spread to Tanganyika, Uganda, Nyasaland and Kenya, and had reached the east coast of Africa.

In March 1953, the rust was detected in violent epidemic form at various widely separated places in Mauritius, and in May last I identified the disease in the neighbouring French island of Réunion, which I was visiting on a short mission.

In a letter dated September 29 last, the Director of the Phytopathological Laboratory of the Pasteur Institute of Tananarive informed me that he had newly identified the disease in certain districts along the east coast of Madagascar, the attack in one of the regions having been observed as from March 1953; but it was stated that there were no records of recent maize importations in Madagascar.

In Mauritius, legislation was promulgated in February 1951 prohibiting the importation of maize from the then affected West African areas and territories bordering them. Maize meal is, however, regularly introduced from Kenya by the military authorities for feeding the Askari soldiers stationed in the island since the Second World War; and washings from contaminated meal could account for

initial foci of infection in a new area. There does not, however, seem to be very strong reasons for considering that the disease was introduced into Mauritius in the Kenya consignments, unless it already existed in that country some time prior to its detection in 1952.

Réunion is about four hundred miles off the east coast of Madagascar and Mauritius one hundred miles farther eastward. Together with Rodrigues, four hundred miles still farther east of Mauritius, these two islands constitute the Mascarene Archipelago; but there is as yet no record of the presence of *P. polysora* in Rodrigues.

Both Mauritius and Réunion are linked with Madagascar and Africa by regular air services, while Mauritius is one of the fuelling points for Qantas aeroplanes on their route between South Africa and Australia via the Cocos Islands. The presence of *P. polysora* in Mauritius, which is the most easterly point it has yet reached, thus constitutes a menace both to Asia and Australia.

It has also been found in the United States and Canada that the spores of the cereal rusts can be carried in a viable condition by air currents to altitudes more than 15,000 ft. and to distances of several hundreds of miles from their point of origin. This means of spore distribution is now considered by some as possibly accounting for the present rapid spread of *P. polysora* in Africa. Its simultaneous discovery in 1953, for the first time, in Madagascar, Mauritius and Réunion would appear to support the hypothesis of spread by means of air currents.

Geographical Distribution of Mating Types in *Gibberella cyanogena* (Desm.) Sacc.

Gibberella cyanogena, the ascomycetous stage of *Fusarium sambucinum* Fuekel f. 6 Wr., has been previously reported¹ to be bisexual (hermaphroditic) and self-sterile. In other words, single-ascospore and monoconidial cultures of this fungus belong to one or other of two mating types, designated m.t.¹ and m.t.², both of which may function as male and female but are self-sterile. For the production of fertile perithecia under laboratory conditions it is necessary to bring together cultures of the two mating types and maintain them under the appropriate environmental conditions.

The examination, by mating tests, of mass cultures of the *Fusarium* stage of this fungus that were

Geographical area	Habitat	State of fungus	Mating type
Canada			
British Columbia	potato tubers	<i>Fusarium</i>	m.t. ¹
Alberta	"	"	"
Saskatchewan	"	"	m.t. ¹ and m.t. ²
Manitoba	"	"	separately
New Brunswick	"	"	m.t. ¹
Prince Edward Island	"	"	m.t. ¹ and m.t. ²
England	<i>Polyporus rickii</i> DeVr.	<i>Gibberella</i>	separately
			m.t. ¹ and m.t. ²
New Zealand			
Scotland	wheat	<i>Fusarium</i>	m.t. ¹
Tasmania	<i>Vicia</i> sp. hops	"	m.t. ¹

isolated from decaying potato tubers in Canada as well as from additional habitats in other geographical areas has revealed that the two mating types occur separately in Nature. In no instance were the two mating types found occurring together in the same mass isolate of the *Fusarium* stage. Their occurrence together in Nature has so far been determined only from a single collection of the *Gibberella* stage. In the accompanying table is shown the geographical distribution, and habitats, of the two mating types in *G. cyanogena* so far determined by me.

The ability of the two mating types to become established separately in Nature would appear to explain why *Gibberella cyanogena* has so far not been encountered in Canada, where *Fusarium sambucinum* f. 6 is widely distributed.

Microflora of Crêpe Rubber

COMPARATIVELY little is known about the micro-fungi normally present on the surface of native crêpe rubber. Brown¹ isolated two chromogenic penicillia and a *Fusarium* from discoloured areas of spotted crêpe. Fullerton² attributed the spotting of smoked sheet and crêpe to species of *Aspergillus*, *Penicillium*, *Fusarium* and unidentified bacteria. Schade³ obtained *Monascus ruber* and *M. purpureus* from smoked sheet. More recently, Shaposhnikov *et al.*⁴ isolated four species of *Aspergillus* and three species of *Penicillium* from smoked sheet, and obtained vigorous growth from inoculations with other common surface moulds.

As a part of a programme of research on the application of bactericides and fungicides to raw and vulcanized rubbers, initiated by the Rubber Service Laboratories of I.C.I., Ltd., in collaboration with ourselves, samples of discoloured crêpe, obtained from Ceylon⁵, were incubated in moist chambers at 25° C., and the resulting colonies of fungi were subcultured on 2 per cent malt agar until pure cultures of each infecting species were obtained. The pure cultures were grown on 2 per cent malt and Czapek-Dox agars and on pieces of crêpe rubber sterilized by steam or methyl alcohol vapour. The species isolated and their behaviour on subculture are listed in the accompanying table.

FUNGI ISOLATED FROM CRÊPE RUBBER

Original discolouration	Micro-organisms isolated from discoloured area	Colour on malt agar	Discolouration of inoculated crêpe
Black	<i>Cladoglyphus herbarum</i> (Pencoon) Link	black	black
Blue-black	<i>Helminthosporium</i> sp. <i>Syncephalastrum</i> sp. <i>Penicillium italicum</i> Sopp Black pycnidia (unident.)	black grey red black	black grey brown —
Brown	<i>Penicillium chrysogenum</i> Bourge	red	brown
Yellow-brown	<i>Margarinomyces halophilus</i> van Beyma	black	black
Orange	<i>Beauveria subtilis</i> Cohn <i>Penicillium citrinum</i> Thom <i>Penicillium variable</i> Sopp <i>Penicillium purpurogenum</i> Stoll	— yellow orange red	— yellow brown-pink red
Violet	—	—	—
Green	—	—	—

Repeated culture of the green- and violet-stained rubbers produced no fungal growth; unidentified bacteria were isolated from the violet-stained rubber. The commonest infection was from *Penicillia*, particularly the species *variable*, *chrysogenum* and *citrinum*. Several strains of *P. citrinum* were isolated of varying chromogenic power. Red stains apparently due to *P. purpurogenum* occurred with some frequency; *P. italicum* was found on a single culture only.

The species of *Penicillium* present on the rubbers are recorded as common in tropical and subtropical areas, and have been isolated in these areas from deteriorating military equipment.

The wide variety of infecting organisms confirms the views of Shaposhnikov *et al.* that unvulcanized rubbers can support the growth of most common microfungi and that infection is airborne during the drying of the crêpe sheet.

Thanks are due to the Rubber Research Institute of Ceylon, which provided the samples of discoloured crêpe for examination.

Poetry and Science

IF the report in *Nature* of January 16 of the discussion at the Penn Club on "Poetry and Science" is accurate, some interesting confusions seem to have arisen. We are told that poets and scientists were antagonistic in the past, because they were under the mistaken impression that there was a real external world—so Prof. H. Dingle. Stephen Spender demanded the right to a subjective knowledge of truth—as if 'knowing' could ever be wholly objective. G. S. Fraser insisted that poetry has its own criteria of exactness—which no scientist could possibly dispute. Mr. N. W. Pirie is reported to have said that scientists discard statements they dislike—surely with some indication of the criteria which, if not satisfied, arouse his dislike.

It must be obvious that both poet and scientist have their own disciplines for exploring human reactions to the world they live in, that these disciplines can be studied, and a methodology of science and of poetry worked out and compared, and seen in their complementary aspects. One gained the impression, from the report, of a confused battle between the Subjectives and the Objectives with Prof. Dingle above the storm, content to know that the battle was taking place in a non-existent universe. That unreality is, at any rate, some consolation to those of us who try to live rationally in this world.

FORTHCOMING EVENTS

(Meetings marked with an asterisk * are open to the public)

Monday, March 15

SOCIETY OF CHEMICAL INDUSTRY, CROP PROTECTION PANEL of the AGRICULTURE GROUP (in the Rooms of the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. R. L. Wain: "Some Recent Developments in the Field of Plant Growth Substances".

UNIVERSITY OF LONDON (in the Chemistry Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. J. M. Bijvoet (Utrecht): "The Structure of Optically Active Compounds in the Solid State: and some other Problems". (Further Lectures on March 17 and 19.)*

INSTITUTE OF METAL FINISHING (in Room 153, Connaught Building, Northampton Polytechnic, St. John Street, London, E.C.1), at 6 p.m.—Mr. P. Spuro: "Recent Developments Concerning Electroforming of Moulds".

BRITISH SOCIOLOGICAL ASSOCIATION (at the Royal Society of Arts, 6 John Adam Street, Adelphi, London, W.C.2), at 8 p.m.—Mr. Tom Harrison: "Bolton and Borneo—15 Years of 'Overheads'".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Lieut-Colonel Sir Rupert Hay: "The Persian Gulf States and Their Boundary Problems".

Tuesday, March 16

UNIVERSITY OF LONDON (in the Anatomy Theatre, Communication Research Centre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. D. B. Fry: "The Experimental Study of Speech".*

BRITISH ORNITHOLOGISTS' UNION (in the Meeting Room of the Office of the Zoological Society of London, Regent's Park, London, N.W.1), at 6 p.m.—Annual General Meeting.

ROYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. F. H. Carey: "The Development of the Spill Flow Burner and its Control System for Gas Turbine Engines".

SHEFFIELD METALLURGICAL ASSOCIATION (joint meeting with the REFRACTORIES ASSOCIATION OF GREAT BRITAIN and the INSTITUTE OF CLAY TECHNOLOGY, at the Grand Hotel, Sheffield), at 7.30 p.m.—Dr. A. T. Green: "Dr. Mellor—His Life and Work".

Wednesday, March 17

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. E. D. Adrian, O.M., F.R.S.: "Recent Developments in the Study of the Sense Organs" (Trueman Wood Lecture).

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. A. Kingsley Wells and Mr. A. Olive Bishop: "An Appinito Fades Associated with Certain Granites in Jersey, Channel Islands"; Dr. J. D. Lawson: "The Geology of the May Hill Inlier".

ROYAL METEOROLOGICAL SOCIETY (at 40 Cromwell Road, London, S.W.7), at 5 p.m.—Scientific Papers.*

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY, SOCIAL PHILOSOPHY SECTION (in the Portico Library, 57 Mosley Street, Manchester 2), at 5.30 p.m.—Discussion on "Social Problems of the Welfare State".

PHYSICAL SOCIETY, LOW TEMPERATURE GROUP (at the Science Museum, South Kensington, London, S.W.7), at 5.30 p.m.—Symposium on "Hydrogen Liquefaction".

Thursday, March 18

BRITISH PSYCHOLOGICAL SOCIETY, INDUSTRIAL SECTION (in Room 105, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 1 p.m.—Prof. L. S. Hearnshaw: "Attitudes to Work" (Chairman's Address).

PHYSICAL SOCIETY, OPTICAL GROUP (in the Physics Department, Imperial College, Imperial Institute Road, South Kensington, London, S.W.7), at 2.30 p.m.—Annual General Meeting. Mr. W. N. Sproson: "A New Photo-electrical Optical Test Bench"; Mr. L. C. Jesty: "Recent Developments in Colour Television".

SOCIETY OF CHEMICAL INDUSTRY, MICROBIOLOGY GROUP (at the Chemical Research Laboratory, Colindale Avenue, Hendon, Middlesex), at 2.30 p.m.—Scientific Papers.

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Meeting for Election of Fellows. 4.30 p.m.—Mr. E. F. Bowden, F.R.S., and Mr. P. H. Thomas: "The Surface Temperature of Shifting Solids"; Mr. R. F. King and Mr. D. Tabor: "The Strength Properties and Frictional Behaviour of Brittle Solids".

INSTITUTE OF MINING AND METALLURGY (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. G. Chad Norris: "Some Grinding Tests with Spheres and Other Shapes"; Mr. G. Lowe Fain: "A Method of Predicting the Performance of Commercial Mills in the Fine Grinding of Brittle Materials".

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. J. G. Hawkes: "Taxonomic Studies on the Tuber-bearing Solanum".

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. F. E. Bomall: "Endomorphisms of Partially Ordered Vector Spaces".

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDINGS MATERIALS GROUP (in the Lecture Hall, Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6 p.m.—Mr. O. van der Poel (Amsterdam): "A General System Describing the Visco-elastic Properties of Bitumens and their Relation to Routine Test Data".

INSTITUTE OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.30 p.m.—Sir Christopher Hinton: "Atomic Energy Made Easy".

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at the Royal Army Medical College, Millbank, London, S.W.1), at 7.30 p.m.—Laboratory Meeting. Chairman: Dr. F. Norman White.

Thursday, March 18—Friday, March 19

SOCIETY OF CHEMICAL INDUSTRY, CHEMICAL ENGINEERING AND FOOD GROUPS (at the Wellesome Research Institution, 183 Euston Road, London, N.W.1), at 10 a.m. daily.—Conference on "Chemical Engineering in the Food Industry".

Friday, March 19

SOCIETY FOR WATER TREATMENT AND EXAMINATION (in the Library of the Water Examination Department, Metropolitan Water Board, Rosebery Avenue, London, E.C.1), at 9.30 a.m.—Annual General Meeting, followed by Scientific Papers.

INSTITUTE OF PETROLEUM (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 2.15 p.m.—Symposium on "Metal-Working Oils".*

INSTITUTE OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Annual General Meeting.

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. N. Pevsner: "Sir Christopher Wren".

Saturday, March 20

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, SCIENTIFIC AND TECHNICAL GROUP (in the Clarendon Laboratories, Oxford).—Whole Day Conference on "Photochemistry and Photography".

BIOCHEMICAL SOCIETY (in the Department of Biochemistry, University College, Gower Street, London, W.C.1), at 10.45 a.m.—Annual General Meeting, followed by the reading of Scientific Papers.

BRITISH PSYCHOLOGICAL SOCIETY (in the Psychology Department, University College, Gower Street, London, W.C.1), at 2.30 p.m.—Dr. W. Mays: "Piaget's Genetic Theory of Concept Formation".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

PHYSICIAN and ENGINEER, Scientific Officer, Experimental Officer, or Assistant Experimental grades, at the Ministry of Supply Experimental Establishment, near Salisbury, Wilt.—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.45/344 (March 20).

LECTURER IN PHYSICS—The Secretary, Birbeck College, Malet Street, London, W.C.1 (March 23).

SCIENTIFIC OFFICER, Grade 8 (with a degree in mechanical or aeronautical engineering, or equivalent qualifications, together with experience in the conduct of aerodynamic investigations, preferably of supersonic flight), at the Long Range Weapons Establishment, Salisbury, South Australia, to undertake investigations of an aerodynamic nature concerning supersonic guided missiles—The Senior Representative (A.P.F.), Department of Supply, Australia House, Strand, London, W.C.2 (March 23).

SCIENTIFIC OFFICER or SENIOR SCIENTIFIC OFFICER (with first- or second-class honours degree or equivalent qualification in physics, chemistry or metallurgy) for development work on carbon for nuclear reactors, involving structural studies of porous solids—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Berkshire (March 23).

ASSISTANT LECTURERS IN BOTANY (preferably with special qualifications in microbiology), ORGANIC CHEMISTRY, PURE MATHEMATICS, PHYSIOLOGY and ZOOLOGY—The Secretary, Birbeck College, Malet Street, London, W.C.1 (March 26).

LECTURER (with special qualifications and experience in the field of vocational selection, guidance and training) in the DEPARTMENT of PSYCHOLOGY, to be responsible for vocational courses leading to a newly established postgraduate Diploma in Applied Psychology—The Registrar, The University, Liverpool (March 26).

ASSISTANT OFFICIAL ANALYSE (with at least an honours degree in chemistry, or the A.B.L.C. Diploma, and preferably with a knowledge of French)—The Greffier of the States, States Greffe, Jersey, Channel Islands (March 31).

LECTURER IN AGRICULTURAL BOTANY—The Secretary of University Court, The University, Glasgow (March 31).

LECTURER (with an honours degree in petroleum production engineering, chemical engineering, mechanical engineering, or geology, with postgraduate or industrial experience in engineering) in PETROLEUM PRODUCTION ENGINEERING, in the Chemical Engineering Department—The Registrar, The University, Edgbaston, Birmingham (March 31).

SCIENTIST (with first- or good second-class honours degree or equivalent in physics, engineering, mathematics or statistics, and several years industrial or laboratory research experience) in the FIELD INVESTIGATION GROUP, Scientific Department, to lead a team carrying out field work at collieries—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/750 (April 8).

SENIOR LECTURER IN AGRICULTURAL BOTANY at the University College of the Gold Coast—The Secretary, Inter-University Council, 1 Gordon Square, London, W.C.1 (April 8).

SENIOR LECTURER in the TEACHING OF PHYSICAL SCIENCE—The Secretary, University of London Institute of Education, Malet Street, London, W.C.1 (April 10).

CHAIR OF THEORETICAL PHYSICS, tenable at King's College—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 18).

RESEARCHER IN PHYSICS and PHYSICIST at Ministry of Supply Experimental Establishments, at Farnborough, Havant, Malvern, Stevenage, and elsewhere, mainly in southern England, for research, development or design of telecommunications and radar equipment, guidance and control systems, instrumentation for variety of research problems—The Ministry of Labour and National Service, Scientific and Technical Register (K), 26 King Street, London, S.W.1, quoting D.490/58A (April 13).

LECTURER IN THE SHERLOCKHOLME SCHOOL OF PHYSIOLOGY—The Dean of the Medical School, St. Thomas's Hospital, London, S.E.1 (April 14).

LECTURER/SENIOR LECTURER IN MATHEMATICS (Pure Mathematics) at the University of Sydney, Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Sydney, April 17).

UNIVERSITY LECTURERS, and UNIVERSITY ASSISTANT LECTURERS IN THE FACULTY OF MATHEMATICS—The Secretary, Faculty of Mathematics, University of Cambridge, The Arts School, Bennet Street, Cambridge (April 30).

TURNER AND NEWALL RESEARCH FELLOW IN ENGINEERING, INORGANIC CHEMISTRY or PHYSICS, or other allied science—The Registrar, The University, Leeds 2 (April 21).

CHAIR OF GEOGRAPHY—The Secretary, The University, Edinburgh (April 30).

RESEARCH FELLOW IN PURE SCIENCE at the University of Durham—The Secretary, 38 North Bailey, Durham (April 30).

LEVERHULME STUDENTSHIPS and SMITH STUDENTSHIPS IN CHEMICAL ENGINEERING—The Registrar, University College London, Gower Street, London, W.C.1 (May 15).

BROUGHTON (with at least a good second-class honours degree with appropriate postgraduate experience) at the West African Fisheries Research Institute, Sierra Leone—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting ODH197/194/01.

DEMONSTRATOR IN ORGANIC CHEMISTRY and DEMONSTRATORS IN INORGANIC CHEMISTRY—The Registrar, The University, Nottingham MASTER TO TEACH PHYSICS up to University Scholarship standard—The Headmaster, 84 Bees School, Cumberland.

METALLURGIST (with an honours degree in metallurgy, or Associate-ship of the Institute of Metallurgists, or equivalent qualification) to control a team of professional and technical grades employed on a production unit involving metallurgical processing of unusual metals—The Administrative Officer, Recruitment, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. 21/W.G.M.

GRANTS & SCHOLARSHIPS

HUDDERSFIELD TECHNICAL COLLEGE

WOOL TEXTILE RESEARCH COUNCIL FELLOWSHIP AND SCHOLARSHIPS
Applications are invited for (1) A Fellowship Research on Woolen Yarn Manufacture, annual value £500 to £700, according to qualifications. (2) Three Scholarships (annual value £00) for research on (a) absorption of mordants, (b) dyestuffs for testing colour vision, (c) structure of cloths. The awards are tenable normally for period of one to three years. Applicants should have university degree or equivalent technological qualifications.

Further details from the Principal, Technical College, Queen Street South, Huddersfield.

H. GRAY,

Chief Education Officer

WYE COLLEGE

(UNIVERSITY OF LONDON)
POSTGRADUATE STUDENTSHIP

The Governing Body of Wye College invites applications for a Postgraduate Studentship in Crop Botany tenable for a period of two years. The award will be in the range of £275 to £350 per annum, according to qualifications. An interest in applied plant physiology is essential. Applications from students graduating in June, 1954, will be considered.

Further particulars may be obtained from the Registrar, Wye College, near Ashford, Kent.

BRITISH EMPIRE CANCER CAMPAIGN invites applications from suitably qualified British subjects for exchange Fellowships in cancer research during 1954-55. Fellowships are of one year's tenure in the United States of America, a stipend of \$4,000 per annum, which will be paid by the American Cancer Society. Travel expenses to and from centre of work will be borne by the Campaign. The closing date for receipt of applications is April 1, 1954. For further particulars and application forms apply to the Secretary-General, British Empire Cancer Campaign, 11 Grosvenor Crescent, Hyde Park Corner, London, S.W.1.

THE ROYAL SOCIETY

STOTHERT RESEARCH FELLOWSHIPS

Applications are invited by the Council of the Royal Society for two Stothert Research Fellowships in the field of medicine, including the sciences on which medical knowledge is based. Each Fellowship will be tenable in any hospital, medical school or other appropriate research institution or university department in the British Isles, or at any other place approved by the Council of the Royal Society. Candidates, who must be of British nationality, should supply the usual personal details and give the names of two referees. Testimonials will not be considered. Applicants and referees at a distance may write direct to the address given below, without first obtaining forms. The subject of the proposed research, and the place at which it would be carried out, together with the name of the Head of the Department, should be given. The appointments will be for two years in the first instance, from October 1, 1954, and may be renewed annually up to a total of four years. The stipend will be £600 per annum, with increments of £50 per annum, and superannuation benefits to which the successful candidate will be required to contribute 5 per cent of annual stipend and to which the Society will make a contribution of 10 per cent.

Applications should be made on forms to be obtained from the Assistant Secretary, The Royal Society, Burlington House, London, W.1, and should be received as early as possible, and not later than April 30, 1954.

UNIVERSITY COLLEGE

LONDON (GOWER STREET, W.C.1)

Leverhulme Studentships (£400 per annum) and Shell Studentships (£350 per annum) in Chemical Engineering, tenable for one session (renewable for second session) are awarded to graduates in chemistry or engineering for advanced training or research in chemical engineering in the Ramsey Memorial Laboratory. Applicants for Leverhulme awards must have industrial experience. Applications, giving particulars of academic qualifications and industrial experience, with names of two referees, must be received by Registrar by May 15, 1954.

THE ROYAL SOCIETY

ALAN JOHNSTON, LAWRENCE AND MOSELEY RESEARCH FELLOWSHIP

Applications are invited by the Council of the Royal Society for the Alan Johnston, Lawrence and Moseley Research Fellowship into the problems of human and animal health and diseases, and the biological field related thereto. The Fellowship will be tenable at any place approved by the Council of the Royal Society. Candidates should supply the usual personal details, and give the names of two referees. Testimonials will not be considered. Applicants and referees at a distance may write direct to the address given below, without first obtaining forms. The subject of the proposed research and the place at which it would be carried out, together with the name of the Head of the Department, should be given. The appointment will be for two years in the first instance, from October 1, 1954, and will be renewable up to a maximum of five years. It will be subject to the conditions governing Royal Society Research Appointments. The stipend will be £1,000 per annum, with annual increments of £75 per annum, with superannuation benefits to which the successful candidate will be required to contribute 5 per cent of annual stipend and to which the Society will make a contribution of 10 per cent.

Applications should be made on forms to be obtained from the Assistant Secretary, The Royal Society, Burlington House, London, W.1, and should be received as early as possible, in any case not later than April 30, 1954.

BALLIOL COLLEGE

OXFORD

JUNIOR RESEARCH FELLOWSHIP

The College proposes to elect a Junior Research Fellow in Mathematics or some branch of the Physical or Biological Sciences as from September 29, 1954.

Applications should be received not later than April 30, 1954. Further details may be obtained from the College Secretary.

A short history of graticules—No. 2

Half-thou. in 1666!

We have told of the wire trellis invented by the Marquis de Malvasia which was used to observe the eclipse of 1666. Later in 1666 Auzout improved on the Marquis' trellis by making a movable wire pass in front of it in order to facilitate measurements and, in a letter he wrote in December of that same year, he described how he was able to sub-divide a foot into between 24,000 and 30,000 parts. The trellis consisted of equally spaced hairs mounted with wax on a brass chasais with a mobile hair passing in front.

Later, Petit simplified this pattern to a micrometer consisting of two wires moving in opposite directions, thus combining Gascoigne's original invention with that of Auzout.

'SPEEDIVALVE'

HIGH VACUUM
DIAPHRAGM VALVE

The well-known Saunders Valve Organisation in co-operation with Edwards high vacuum engineers have designed this important new valve for high vacuum work which offers the following outstanding features :

Manufactured in
the following bore
sizes:

$\frac{1}{4}$ ", $\frac{1}{2}$ ", $\frac{3}{4}$ ", 1", 1 $\frac{1}{2}$ ", 2"

★ Vacuum tightness and freedom from spindle leakage with a specially designed wear-resisting diaphragm

★ No moving parts to wear.

★ When open 'SPEEDIVALVES' give unrestricted pipe line flow.

★ Easily assembled into vacuum system VALVES UP TO 1 INCH HAVE INTEGRAL EDWARDS RAPID-ASSEMBLY UNIONS WITH 'O' RING SEALS. Larger sizes are specially flanged to receive ring type seals.

★ The 'SPEEDIVALVES' up to 1 in. dia. constructed in high finish die-cast, mercury resistant light alloy for clean vacuum tight body.

BROADCASTING AND TELEVISION: MONOPOLY OR COMPETITION?

THE stimulating address on some problems of communication which Barbara Wootton delivered to the Aslib Conference at Nottingham last autumn was essentially a plea for the use of the right tool for the right purpose. Its analysis of the way in which channels of communication may be blocked, and particularly of the difficulty in the way of communicating exact or quantitative knowledge, has a profound bearing on the current discussion of the future of television and even of broadcasting itself. Prof. Wootton could point to some striking illustrations of the inefficiency of broadcast talks, and even of the limitations of written communication where mathematical precision or quantitative expression is demanded; she thinks it is doubtful whether the average citizen understands more than about a quarter of such a broadcast talk as those given in the series "Topic for To-night", and that quarter may well be a random collection of the ideas presented to him, in which subsidiary points may figure unduly.

The limitations are set, not so much by the imperfections in the technique of the broadcaster, as by the intelligence of the listener, and, as Prof. Wootton well indicates, this position plays into the hand of the emotional broadcaster, even where precision is essential in order to afford a sound judgment. Nor will the difficulty be resolved merely by drawing a sharper line between objectively established fact and subjective speculation, important as is that distinction. Seen from the point of view of adult education, the imaginative art must be enlisted to secure from the listener or reader or viewer the educational effort and the mental co-operation which are indispensable to a clearer understanding of questions of fact whether in social science, in public affairs or in any other field of human knowledge and endeavour.

In this position lies the real danger which may arise when broadcasting and television are regarded on any other level than that of a public service. Because neither broadcasting nor television in itself demands more active co-operation from listener or viewer than the turning of a knob, they can all too easily encourage the passive receptivity that offers the great danger to standards of public taste. Now that the Television Bill has been published, it is important to consider carefully the issues that are raised.

"Television", as the Government's White Paper, quoting from the report of the Beveridge Committee, admits, "has great and increasing power in influencing men's minds"; but that power, unless exercised responsibly and imaginatively, confirms men in their passivity and prejudices rather than uplifts and enlightens them. Evidence enough of this tendency was quoted in the parliamentary debates nearly four months ago on the Government's proposals and in Lord Simon's recent book "The B.B.C. from Within"*, and the educational aspect of these two media of

* The B.B.C. from Within. By Lord Simon. Pp. 300. (London: Victor Gollancz, 1953.) 10s. net.

communication is of such vital importance that it overshadows completely the question of monopoly.

On this point there are two passages in Lord Simon's book which should be noted. In cultural matters, he points out, the B.B.C. has great influence; it does consciously seek—and often with outstanding success—to raise standards and to create new tastes. In politics and in religion, however, it is entirely neutral; its broadcasts are proportional to the demands of organized public opinion and it has no power and shows no initiative, except in freely encouraging to the very best of its ability the broadcasting of information, opinion and discussion by leaders of thought in all religious and political fields. Lord Simon dismisses as unfounded the idea that the B.B.C. is dangerously powerful. Its influence is great and its practice and policy sufficiently diversified to secure reasonable freedom on the air, if not sufficiently so to satisfy all minorities. He regards its influence on the whole as promoting, through its news, talks, discussions and features, an informed and responsible British democracy, more tolerant and wiser than many others.

That much lies to the credit of the public service ideal, though even here the danger is not excluded that broadcasting as well as television, if too much time is given to it, may prove inimical to the formation of independent-thinking citizens of democracy. That danger is bound to be greater if either passes under the influence or control of commercial interests, whose concern with public service is a secondary matter, and whose dependence upon advertising for revenue renders sales promotion a dominant motive. Such a self-denying ordinance as the exclusion of sensational television between the hours of six and eight in the evening is too much to expect in these conditions. Commercial television or broadcasting might conceivably assist the introduction of a higher standard of political commentator. The failure of the B.B.C. to use regular political commentators and so to build up their influence is cited by Lord Simon as evidence of the B.B.C.'s impotence to influence opinion in public affairs in any given direction. Commercial television or broadcasting might remedy this defect of monopoly and facilitate the introduction of commentators of the standard of the best of American commentators. It could equally open the door to the more sensational and irresponsible, and this disadvantage of monopoly may well be corrected more widely by some other means such as the alternative public service concerns, towards which Lord Simon himself leans.

Hitherto, in Great Britain, the existence of monopoly has been consistent with the responsible exercise of influence rather than power in broadcasting. The British Broadcasting Corporation has discharged its trust in a way which has won almost universal tribute. Nevertheless, the debate on monopoly was opened rather than closed by the report of the Beveridge Committee, and the alternatives to the present system are the subject of objective, as well as subjective, inquiry and discussion. Concern, moreover, at the effects of broadcasting and

television on society has sharpened anxiety about the possible consequences of their influence being exerted by any bodies other than those whose first responsibility is to provide a public service. In television and in broadcasting we have techniques which, wisely used, could, as Lord Simon's book indicates, be educational instruments of untold benefit to mankind. To them indeed apply the words with which H. A. L. Fisher, in 1935, closed the third volume of his "A History of Europe": "The developing miracle of science is at our disposal to use or abuse, to make or to mar. With science we may lay civilization in ruins or enter into a period of plenty and well-being the like of which has never been experienced by mankind". When Fisher wrote that, an insane racialism threatened, as he put it, to rupture the seamless garment of civilization. The rents have not yet been closed nor the wounds healed, and this question of television and broadcasting underlines his plea that we should replace our squandered treasures of humanity, toleration and good sense.

It is therefore not surprising that the vice-chancellors of thirteen universities of Britain should have recorded their conviction in a letter to *The Times* that to place television on a commercial basis, which must mean that the programme is determined by the criterion not of merit but of popularity, would be to throw away an instrument with very great possibilities for good. Informed opinions differ as to how much positive harm is done to the young by commercial television in other countries; but, as the vice-chancellors rightly point out, we have recently recognized in the television of the Queen's coronation the power of television for good, and if we deliberately discard that power we can never hope to recover it, and in this view the vice-chancellors have received strong support from other educational associations. The National Union of Teachers, the Workers' Educational Association and the Association of Education Committees, for example, have all made written representations on commercial television to the Minister of Education.

The debate which took place in the House of Lords on November 25 and 26 gave further indication that many thoughtful people are unalterably of the opinion that to commercialize television would mean both a danger, especially to the young, and a loss of great opportunities for good. That expression of opinion was virtually ignored by Government spokesmen in the Parliamentary debates, and on December 14, in a further letter to *The Times*, the vice-chancellors, while welcoming the Government's pledge against direct sponsoring, urged that the power of television was enormous and that any system which would permit commercial considerations to exercise a determining influence on programmes was most unwise. It would, in fact, have been a dereliction of duty if, as responsible leaders in education, they had not reaffirmed their strong and continuing belief that such a risk should be avoided.

An impressive feature of the report of the Beveridge Committee was that, in spite of an unconcealed distrust of monopoly, the Committee, with one dissentient,

recommended the continuance of the monopoly of the British Broadcasting Corporation as the lesser of two evils. It is now clearer than two years ago that the debate on monopoly has only begun: it is equally clear that, among those who are most alive to all that is involved, there is as yet no general agreement as to the wisest alternative to monopoly—in broadcasting or in television. For this reason the Archbishop of Canterbury's appeal to the Government that it should recognize that its proposals are by no means the only ones, that there may be better alternatives, that the real object should be an agreed solution which will satisfy the great majority of the nation, and that until that search has been made and failed the party machine should not be invoked, found strong support not only in the debate from Lord Beveridge himself, Lord Layton, Lord Waverley and others, but also outside the House. Thus the statement by the Assistant Postmaster-General, Mr. L. D. Gamman, that in preparing legislation the Government would consider carefully and sympathetically any alternative practicable proposals for terminating the B.B.C. monopoly, and the declared objective of the policy indicated in the White Paper on Television Policy "to proceed with caution into this field and to safeguard this medium of information and entertainment from the risk of abuse or lowering of standards", were welcomed.

Nevertheless, there is justification for the belief that the Government has given way to commercial interests and jeopardized the whole future of broadcasting and television in Great Britain. Nothing that was said in the Parliamentary debates by Government spokesmen touched this issue: the argument was never met. Moreover, doubts as to Government intentions and good faith were fanned by another omission. The second objective of television policy was defined in the White Paper as "to reduce to a minimum the financial commitments of the State". The previous White Paper on Broadcasting stated that "in the expanding field of television provision should be made to permit some element of competition when the calls on capital resources at present needed for purposes of greater national importance should make this feasible". On the question as to how far the diversion of resources to the expansion of television is at present justified, the White Paper on Television Policy and Government spokesmen in Parliament were silent. Taken with the Government's implied intention to continue to deduct part of the British Broadcasting Corporation's licence income, the Government's attitude on the financial and materials aspect of television is thoroughly unrealistic. The grave doubts and reservations on these points expressed by the Archbishop of Canterbury and Lord Waverley were completely ignored.

The Archbishop of Canterbury, referring to these passages in the two White Papers, asked how far it is wise at this time to put much more of our national financial and other resources into intensifying the output and accelerating the development of television. It seemed to be taken for granted by Government spokesmen, as well as by others, that the purposes of greater national importance are so well supplied

with capital resources that those resources can now be diverted to the lesser purpose of competitive television. That is not a view which is likely to be shared by those who are concerned with the country's effort in scientific and technical research, and the calls which the development of atomic energy is already making on resources. In materials, as well as in trained man-power, the expansion of television is likely to compete for resources which are already failing to meet the full requirements of the Department of Scientific and Industrial Research, the universities, and industry. So far as buildings and equipment are concerned, the condemnation of the policy of both political parties in regard to schools and technical education contained in two recent reports from the Select Committee on Estimates makes nonsense of any proposals for the expansion of television until the glaring defects revealed in these two reports are in the way of being removed by appropriate allotment of the necessary resources of capital and materials, while road development might also reasonably be expected to have a prior claim.

Lord Waverley said little on this particular point; but his comment that there is at least a danger that more and more entertainment in the present circumstances may mean less and less effort left no doubt as to his misgivings. Certainly neither the Chancellor of the Exchequer nor his predecessor in that office, Mr. Hugh Gaitskell, had encouraged the belief that we can yet afford to divert national resources into the production or development of luxuries, such as is television on any serious and responsible view. Prudent consideration of available resources suggests the impartial exploration on non-party lines of the possibilities of terminating monopoly and securing the real advantages of competitive television without the dangers that dependence on revenue from advertising appears to involve.

This position gives further force to some comments of the Archbishop of Canterbury and others on the question of the licence fee for television. The Archbishop's suggestion that the licence fee should be raised as necessary to enable the B.B.C. alone to do its job well or to permit an element of competitive programmes, found support from all sides, even from those who are also prepared to experiment with advertising; and Lord Salisbury's rejection of such a suggestion ignored the Archbishop's sound comment that the licence fee should be such that people paid for what they got and did without amenities for which they could not pay. Nor did Lord Salisbury meet the point that if advertisements were introduced the revenue obtained from them should be used for subsidizing the whole service and thus avoid prejudicing hopelessly the position of the B.B.C., or the argument advanced by Lord Merthyr, Lord Moyns and others that the Government should drop its present practice of taking 15 per cent of the B.B.C.'s licence revenue. It is undoubtedly sound that, as Lord Beveridge remarked in supporting the Archbishop of Canterbury, people should pay directly rather than indirectly for their broadcasting or television.

In the early stages of the discussion, Mr. Selwyn Lloyd rejected any compromise except on the condition that an alternative system should draw some revenue from advertisements, but other spokesmen for the Government were not so unreasonable. Early in the House of Lords debate, the Postmaster-General, Earl de la Warr, had indicated the Government's readiness to consider Parliament's views before definite and detailed legislation was prepared, and even in Lord Salisbury's rather hard speech, he said that, within the broad basic principles of the Government's scheme, the Government was prepared to consider any suggestions that might be made. Lord Salisbury referred particularly to the ideas put forward by the Archbishop of Canterbury and by Lord Waverley as worthy of further study, which notably went far outside the conditions afterwards laid down by Mr. Selwyn Lloyd in the House of Commons debate.

Lord Waverley's remarks in particular deserve to be noted. He believes that no one can at present form a true estimate of the ultimate impact of television upon our economic, social and cultural life. In urging that we should wait before making the surrender involved in the Government's plan—a surrender which he is convinced would lead to a lowering of standards—he asked the Government, while accepting the principle of competition and agreeing reluctantly to the establishment of another public corporation, to look again at the finance and other features of its scheme with the view of eliminating dependence upon advertisements. Sir David Maxwell Fyfe's speech in concluding the debate in the House of Commons on December 15 was pre-eminently reasonable, and seems to hold open again the door which Mr. Lloyd had slammed. Sir David's remark, in connexion with monopoly, that the ultimate safeguard of liberty lies in diversity has implications which augur better for second thoughts by the Government on matters on which the spokesmen in Parliament were silent than might be judged from the general trend of the debates.

How important television is likely to become in moulding the civilization of the future cannot yet be judged, nor is a sound judgment likely to be formed in an atmosphere inflamed by party politics or heated argument over monopoly. There is need for much clearer thinking about the responsible exercise of power in a field relatively new and almost uncharted. Even the specific applications of television in education and the techniques demanded are still a matter for experiment, and there is indeed need that, as Lord Layton urged, as far as possible, our ventures into this new field should be made by common consent.

In the Television Bill which has now been laid before the House of Commons an attempt has been made to reach a compromise between the original proposals put forward in the White Paper and the views expressed, particularly in the House of Lords. Thus there are elaborate safeguards against the influence of advertising, and a grant-in-aid of £750,000, to be voted annually by Parliament, is proposed. In any event, it is to be hoped that when the Bill is debated in Parliament there will be

less disposition to challenge the sincerity of those who promote or oppose. The analogies drawn between broadcasting and the Press have shown some confusion of thought, but may nevertheless have been inspired by a sincere concern to secure freedom of thought and expression. So too, on the other side, legitimate concern lest commercial interests would be allowed to control the content and context of broadcasting or television may have been expressed in such a way as to impute motives or conduct to advertisers and business men from which Lord Beveridge explicitly dissociated his Committee. None the less, the danger exists, and in fact has been admitted by the Government, the proposals of which are criticised because they are regarded as providing inadequate safeguards here in a matter in which the public interest must be supreme. An agreed solution should be possible, based on hard constructive thinking and a clear appraisal alike of competing claims on national resources, and of the several alternatives to monopoly in broadcasting and television, which are open to us; among the matters which should be considered are the possibilities of regional stations and various technical advances which are in process of development.

THE PLACE OF RELIGION IN THE SCIENTIFIC WORLD

Religion and the Modern Mind

By Prof. W. T. Stace. Pp. vii+301. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1953.) 21s. net.

PROF. W. T. STACE has recently changed his view of the nature of reality, and this book, together with his "Time and Eternity", published in 1952, gives an account of the change and, to some extent, of the reasons for it. Put in the crudest way, his intellectual conversion might be described by saying that, whereas he formerly believed in only one world, now he believes in two. But this, of course, is an unfair statement of a position which deserves the most respectful consideration. "Religion and the Modern Mind" is brilliantly written, and, though the argument is by no means simple, it can be followed easily by any educated person.

Prof. Stace is concerned with the decay of religion which, he thinks, must mean an impoverishment of human life and experience. He traces this decay to the rise of natural science and exhibits very clearly the stages in the process. He does not hold that the development of science led logically to the waning of religious beliefs, or at least of the belief in God, because no scientific discovery or theory could tend either to prove or disprove Theism; but he believes that the non-logical process of thought can be traced by which a religious view of the universe has steadily lost authority over the modern mind. The progress of the scientific interpretation of experience which has "no need for the hypothesis" of Deity has almost insensibly persuaded men that there is no need for the hypothesis for the conduct of life. The conceptions of a 'world-purpose' and of the world as a 'moral order' have faded out of the consciousness of

multitudes who would be quite unable to give reasons for rejecting them.

The remarkable feature of Prof. Stace's position is that he maintains a naturalistic and determinist position with regard to empirical knowledge. When we look at things from the point of view of science, the whole of existence, including our minds and thoughts, is a deterministic order. But this is not the only way of looking at reality. The important thing that has happened to Prof. Stace is that he has become convinced of the validity of mystical experience. His exposition leads one to suppose, in spite of his disclaimer, that he has not only been convinced but has had some personal initiation into the mystic way. However this may be, he goes to the limit with the mystics. The mystical union, for him, is the only bliss that is really worth having. The symbols and doctrines of the great religions are only shadows of the true Reality. Nothing can be said of what the mystic knows, if knowing is the right word; only that the knowing which is beyond knowledge is the highest good. Prof. Stace does not hesitate to draw the logical conclusion. There is nothing in common between the world of empirical experience and the world of mystical insight. From the point of view of science, mysticism is illusion; and from the point of view of mystical experience, the whole of temporal existence and all the events and objects which science studies are "maya"—deceptive appearance. At one point only do the two orders touch—in the soul of the mystic where the Eternal cuts across the passing and impermanent.

Clearly, this far-reaching statement of a deeply considered view would call for a long discussion. Here it is possible only to point out that mysticism may be of a 'comprehensive' type, and there have been great mystics who have found reflections of the divine Reality in Nature. It is not clear that their experience is less valid than that of the 'exclusive' mystics; and of course, as Prof. Stace is well aware, philosophical difficulties of an insuperable kind arise when we try to think out the implications of this drastic dualism of experience. When God is thought of as 'Wholly Other' we are at a loss to see how He can enter this world or our own lives. Nevertheless, this is a book which deserves to be read both for its masterly presentation of a difficult subject and for the controlled passion which gives life to every page.

W. R. MATTHEWS

CHEMISTRY OF DAIRYING

Richmond's Dairy Chemistry

Revised by Dr. J. G. Davis and F. J. Macdonald. Fifth edition, based on the previous revision by G. D. Elsdon and G. H. Walker. Pp. viii+608. (London: Charles Griffin and Co., Ltd., 1953.) 60s. net.

THIS is a very welcome revision of a book which has been a standard work of reference on dairy chemistry since 1899. The scope of the book has been somewhat widened since the last revision in 1942 by Elsdon and Walker; but the most important features of their edition have been retained. Recent research has added considerably to our knowledge of the constituents of milk, and the present authors have given a comprehensive review of this in Chapter 2. In a book of this nature it has not been possible to give more than a brief summary of

individual researches, but workers who wish to pursue the subject are provided with ample references to original papers, reviews and the titles of recent books on the subject.

A most interesting account is given on the variation in the composition of cows' milk during the past twenty years. This suggests a distinct fall in solids-not-fat, especially since 1939. Provan's figures quoted from his findings in 1949 show a fall in bulk milk from 8.9 to 8.6 per cent. The effect of breed, feeding, climate, health, age, season, etc., is discussed at length in Chapter 3. The freezing point of milk has been fully dealt with as regards its determination and the recent reports of abnormally small depressions. In two of the cases quoted, the depression of the morning milk was normal, but that of the evening milk abnormally small. This appears to have been due to the housing of the cows at night, when they were deprived of water for many hours, the water intake being copious during the daytime. In a third case the cows were kept on a starvation diet.

Useful information is given on the pH of milk and milk products, and comparisons are made between the titratable acidity of milk and the corresponding pH values. The recent work recorded on the factors affecting the keeping quality of milk powders is of considerable commercial importance and has been given due prominence. The chapters dealing with analysis have been augmented by a most useful account of the detection and determination of enzymes, which includes tests for estimating the degree of heating of milk. Other important additions are methods for the determination of metals in dairy products and statutory tests for milk.

As would be expected from authors who have devoted so many years to the subject of dairy chemistry, the present edition gives a most extensive bibliography. Upwards of twelve hundred original works are referred to and form probably the most complete bibliography on the subject yet published. The text, tables, diagrams, etc., are extremely clear, and this revised edition will be indispensable to the dairy chemist for many years.

J. KING

WESTERN SCIENCE IN RESURGENT ASIA

Men Against the Jungle

By Ritchie Calder. Pp. 232+15 plates. (London: George Allen and Unwin, Ltd., 1954.) 15s. net.

THIS book gives a graphic account of the field-work of the specialized agencies of the United Nations Organization in south-west Asia. A striking feature of the account is the speed with which modern science can be applied to the elimination of disease, hunger and illiteracy. One shot of an antibiotic can cure yaws, which in some areas affects the majority of the people. In a few months malaria, which affects practically everybody in badly infested districts, can be eliminated. Freedom from these diseases makes the people so much more vigorous and fitter to cultivate the land properly that their food production can be increased by as much as 15 per cent. Apart from major projects like the Tennessee Valley Authority to increase the area of fertile land, simple methods of improved cultivation, the use of fertilizers and selected seeds can increase the yield by 50 per cent.

The author shows that the elimination of illiteracy needs no elaborate training colleges for teachers. At primitive educational centres, natives are trained and then go back to their villages to teach old and young to read and, what is equally important, take with them an elementary knowledge of, and enthusiasm for, improved hygiene and agricultural methods which the natives can carry out themselves with their own resources.

As the author shrewdly remarks, this method of getting the natives to carry out the development themselves and by the means they understand avoids the mistake of trying to superimpose a 'pre-fabricated' Western civilization on a totally different social and economic structure. By the improvement of environmental conditions the standard of living rises, and as illiteracy disappears there will go with it the stultifying superstitions and fears of evil spirits and local gods which need to be appeased.

Scientists and politicians might well ponder over the ultimate effects of introducing Western technology to the old civilization of the East. The first result will be a fall in the death-rate and an 'explosion of population' such as occurred in England in the nineteenth century, in which case it would be doubled in fifty years. There is no reason for believing that the Asian, even the wild man of Borneo, is innately inferior, physically or mentally, to the white man. The superior technology of the West, especially in armaments, which enabled the European nations, including the offshoot North America, to get military and economic control of practically the whole world is an open book to the Asians, who now have their own universities and research organizations. All Asia may follow the example of Japan, which within forty years of adopting Western technology became a first-class world power. As the late General Smuts pointed out, the upsurge of Asia is by far the most important political event of our day. Compared with it, European problems are of minor importance.

The most important aspect of the introduction of modern technology to the East is the raising of the standard of living and increasing the physical and mental vigour of the masses which constitute more than half the population of the world, by freeing them from the debilitating effects of disease, hunger and superstition. This development, which will profoundly affect the future of human society and which receives little attention from politicians, is being promoted by the work of the specialized agencies of the United Nations Organization described in this book, which is as readable and as fascinating as a thriller. It can be commended to all those who speculate on the shape of things to come in this rapidly changing world.

BOYD ORR

DISSOCIATION ENERGIES OF DIATOMIC MOLECULES

Dissociation Energies and Spectra of Diatomic Molecules

By Dr. A. G. Gaydon. Second edition revised. Pp. xiii+262+4 plates. (London: Chapman and Hall, Ltd., 1953.) 35s. net.

THE twelfth and final chapter of this second edition of Dr. A. G. Gaydon's book is headed: "The Dissociation Energies of Diatomic Molecules; Numerical Values". An extensive compilation of

data follows, covering some 275 molecules. The merit of these tables lies not only in the values recommended, but also in the assessment of the probable error limits to be associated with each of the values given. In comparatively few molecules are the dissociation energies known precisely. Dr. Gaydon lists twenty-two molecules for which the error limits lie within ± 0.01 eV., and there are a further thirty-seven molecules for which the error limits are given as ± 0.1 eV. At the other extreme there are sixty-seven cases in which the error limits range from ± 0.5 to ± 2 eV., and thirty-nine cases where a question mark is attached to the recommended value. Of the dissociation energies given by the author in the first edition, published eight years ago, no less than one-third out of a total of two hundred and fifty are now altered to a greater or lesser extent.

The major revisions in the new edition are to the last four chapters, which have been largely re-written. In these the author deals with several diatomic molecules for which the dissociation energies remain both in doubt and subject to much controversy. These controversies rage most violently in the important cases—practical and theoretical—of the dissociation energies of N_2 and CO, and—in lesser degree—of F_2 and S_2 . Dr. Gaydon joins combat with these issues with spirit and force, and presents his conclusions most persuasively.

I am inclined to agree with Gaydon's choice of values, $D(F_2) = 1.6$ eV., and $D(S_2) = 4.4$ eV. Recent evidence by Doeschner¹ (mentioned, but not elaborated upon, in the book), by Haar and Beckett², and by Barrow³, supports the chosen fluorine value, and the work of Schon⁴ and Porter⁵ is difficult to reconcile with the alternative values (3.3 eV., 3.6 eV.) that have been proposed for $D(S_2)$. The case presented for the value $D(N_2) = 9.76$ eV. is certainly strong, and indeed might have been strengthened further by mention of the studies of Kistiakowsky⁶ on the detonation velocities in mixtures of gases containing cyanogen, oxygen and nitrogen. Nevertheless, some doubts linger, and although the author clearly wins the debate into which he enters, one feels that decisive experimental proof is not yet available.

The problem of the dissociation energy of CO is tied to that of the latent heat of sublimation of graphite, $L(O)$. Dr. Gaydon favours the value $D(CO) = 11.11$ eV., and hence the so-called 'high' value, $L(O) = 170.0$ kcal./mole, but he qualifies his choice with the warning: "it is wise not to be too dogmatic".

Attempts to measure $L(O)$ directly—and these have been several—have now occupied a period of thirty years. This long-standing problem is perhaps fairly to be described as exasperating, for despite careful and determined attacks upon it by able experimentalists, the answer cannot yet be quoted with certainty. But the challenge is being met with vigour, and one feels the problem can scarcely resist solution for much longer. Indeed, the latest studies (Ohpka and Inghram⁷, Honig⁸) would seem to expose the hub of it.

La Chimica delle Fermentazioni

Microbiologia, Enzimologia, Chimica e Tecnica delle Fermentazioni. Da Virgilio Bolcato. Seconda edizione. Pp. xxiii+665. (Bologna: Nicola Zanichelli, 1952.) 5,000 lire.

THIS book is divided into four parts: elements of general microbiology; enzymology; chemistry of fermentations; and technique of industrial fermentations. One of the virtues of the book is the excellent background and perspective to the pith of the dissertation (Part 3) provided by the other parts. In Part 3 itself, not only are modern views on the mechanisms of various fermentations presented, but also older schemes are critically discussed. A further desirable feature is the description of the methane fermentation, which is frequently neglected in text-books.

The main weakness of the book perhaps resides in undue brevity in certain sections, or in actual omissions. Thus, the reviewers feel that, in Part 1, more detailed treatment should be given to the role of micro-organisms in Nature, with particular reference to the carbon and nitrogen cycles. Again, the section on classification of micro-organisms would benefit by precise definition of the bacteria, yeasts and moulds in the organic world, and by some detail of the chief families and genera comprising the bacteria. The production of antibiotics is not treated. Reference is made to quite recent developments in enzyme chemistry, often, however, most briefly, although references are given. Indeed, there are a good, up-to-date bibliography, and subject and author indexes.

Whatever its shortcomings, the virtues of the book far outweigh them. It is unfortunate that this book does not exist in English translation, for it is admirably suitable as a text-book for students of microbiological chemistry and the associated field of plant biochemistry.

R. H. HOPKINS
C. RAINBOW

A School Course In Mechanics

By A. J. Bull. Part 2. Pp. viii+157+408. (Cambridge: At the University Press, 1953.) 15s.

THIS volume, together with its more elementary companion, Part 1, is designed to provide a continuous course reaching the standards required for the papers at Advanced and Scholarship levels for the various General Certificate of Education examinations, though the author states that students wishing to prepare for open university scholarships will need to supplement it by some other book. There is no doubt that, on the whole, the author has admirably succeeded in his aim. There is evidence of a well thought-out plan and a very satisfactory presentation which suggest that Mr. A. J. Bull has great enthusiasm both for his subject and the teaching of it.

In this volume, calculus is, quite properly, used freely, and there is a wide selection of questions, many of university standard; in addition, quite a number of typical questions are fully worked out in the text.

The need for practical work as an integral part of the course is stressed, though it must be said that the author does not approach many of the topics from the experimental aspect. This makes the book severely theoretical, and although those who are more mathematically minded will not be affected, the reviewer feels that an experimental approach to

some of the problems dealt with would be helpful to the more ordinary student. There can be little doubt, however, that in his own teaching practice, Mr. Bull does introduce practical work in support of the text-book theory, and he exhorts other teachers to do likewise.

ASTM-IP Petroleum Measurement Tables

British edition: British (Imperial) Units of Measurement. Prepared jointly by the American Society for Testing Materials and the Institute of Petroleum. Pp. xv+416. (London: Institute of Petroleum, 1952.) 50s.

ONE of the latest joint efforts of the American Society for Testing Materials and the Institute of Petroleum is the publication of "ASTM-IP Petroleum Measurement Tables" (official designations being respectively D 1250 and IP 200), based on collective work started in 1946. The magnitude of the task can be readily imagined when it is realized that this and companion volumes contain thirty-nine tables involving some six hundred thousand six-digit figures (nearly four million digits); well over a quarter of a million IBM cards, weighing more than two tons, were employed in their make-up. These tables meet a demand from the oil industry and are authoritative in a computation of British (Imperial) units of weights and measures. They form part of a trilogy, including volumes devoted to United States and metric systems. The present (British) book includes tables for specific gravity and volume reduction to 60° F., and for weights per unit volume and volumes per unit weight over the gravity range 0.500-1.000, generally at intervals of 0.001. There are twenty-three separate tables in this volume, each of which is preceded with information as to purpose of the table, and also examples of how to use the data given. The completeness and accuracy of these tables are a major credit to all concerned in their compilation and, moreover, ensure a heavy international demand for this work, not only in the petroleum industry but also in a much wider field of applied science.

H. B. MILNER

Alternating Current Wave Forms

Theory and Practice. By Philip Kemp. (Monographs on Electrical Engineering, Vol. 1.) Second edition, revised and enlarged. Pp. xi+406. (London: Chapman and Hall, Ltd., 1952.) 50s. net.

MR. PHILIP KEMP'S book dealing with alternating current wave forms is one of considerable general utility to electrical engineers. It deals with the synthesis and harmonic analysis of complex periodic waves, and with the properties of such waves in relation to electrical networks.

Only elementary mathematics is involved, and the book is very suitable for the use of undergraduate students. A good deal of attention is given to the harmonic-generating properties of circuits with iron-core reactors, and the production of harmonics by cyclic variation of resistance is also considered. Harmonics in polyphase systems and in transformers in various systems of connexion and when supplying rectifiers are treated in two chapters. Two further chapters are devoted to the study of harmonics in the flux waves in electrical machines, and to the generation of harmonic e.m.f.'s in alternating-current windings.

The book gives a good general, but necessarily not detailed, treatment of the main features of the subject, both theoretical and practical.

NATURE CONSERVATION IN BRITAIN

ALMOST exactly five years have elapsed since the Nature Conservancy was constituted by Royal Charter "to provide scientific advice on the conservation and control of the natural flora and fauna of Great Britain; to establish, maintain and manage nature reserves in Great Britain, including the maintenance of physical features of scientific interest; and to organize and develop the scientific services related thereto". It is therefore a matter of some interest that the first two reports¹, one relating to the work of the Conservancy up to September 30, 1952, the second for the year ended September 30, 1953, have recently been published. It is to be hoped that the form of the second of these reports justifies the assumption that, as laid down in Section 24 of the National Parks and Access to the Countryside Act, 1949 (12, 13 and 14 Geo. 6, Ch. 97), the Nature Conservancy will "as soon as possible after the thirtieth day of September in each year, make to the Lord President of the Council a report on the discharge by them of their functions during the period of twelve months ending with that day".

Although to some extent the way has been paved for the Nature Conservancy by the pioneer work of the Royal Society for the Protection of Birds, the National Trust, the Society for the Promotion of Nature Reserves and a few other and more local societies, nevertheless the Nature Conservancy faces a formidable task, and one which seems likely to become more and more difficult of achievement as the impacts of new claims for land, and of modern techniques of land usage, reach their maximum demands. Many of the most interesting species of plants and animals of Britain have already become restricted, as a result of agricultural development and of urbanization, to marginal lands. Now these same retreats are the objects of competition among hill graziers, foresters, new industries and the Armed Forces. Moreover, the Nature Conservancy was constituted immediately following a succession of years during which dramatic changes were imposed upon many areas under the demands of war-time economy. War agricultural committees drained and ploughed much land which had never before been cultivated, huge acreages were disciplined into landing fields, industry was dispersed widely into former rural areas, and battle-practice schools took over many square miles of land as gunnery and bombing ranges or for manoeuvres with armoured vehicles.

It is not surprising, in view of this, that, despite the preparatory work of the Nature Reserves Investigation Committee and, following that, of the Wild Life Conservation Special Committee, it has proved necessary to organize a complete survey of England and Wales in order to determine the conditions now existing, and so to provide, as it were, an up-to-date register of the status of the wild life of the country, and at the same time to determine what measures may now be necessary in order to conserve what we have left of it. It is satisfying to read that such a survey was very nearly complete by 1952, and by September 1953 more than one thousand sites had been listed in England alone as being of sufficient importance to merit notification to local planning authorities under Section 23 of the 1949 Act. The

protection granted thereby is by no means complete, but it ensures that the Conservancy will be consulted before any new development is permitted which may modify the conditions within such a listed area.

In a country so small and densely populated as Britain, the establishment of Nature reserves is not lightly to be undertaken. Land is a scarce commodity, and its use must be fairly and wisely allocated among the many claimants for it. Moreover, the proper maintenance of a reserve for scientific study demands the goodwill and understanding of the public. Some reserves have been maintained for many years, notably under the aegis of the National Trust and by such bodies as the Royal Society for the Protection of Birds, the Society for the Promotion of Nature Reserves and the Norfolk Naturalists' Trust; readers of the present reports will note with satisfaction the mutual co-operation which the Conservancy has established with these bodies. The establishment of new national reserves is proceeding commendably slowly in view of the need for very careful selection. The view expressed in the second report by the Conservancy that this rate is disappointingly slow may be discounted. Eleven sites have been declared in England and Scotland, and another twelve acquired too recently for declaration to have been completed by the end of the Conservancy's year. By far the largest are the Beinn Eighe Reserve near Loch Maree and the Moor House property in Westmorland, both of which comprise some 10,000 acres. The remainder are smaller areas, many of them reserved for their special interest, such as the famous yews of Kingley Vale, the brook conditions of Cavenham Heath, the fens, broads and sand-dunes of various Norfolk and Suffolk sites, and the remarkable broken cliff conditions of the Dowlands landslip in east Devon. Some of these have already been in the care of a national or local society, which has now transferred the trusteeship to the Conservancy; others have been leased or purchased, while yet others, including the sites of both the Piltown and the Swanscombe skulls, have been presented.

Section 21 of the 1949 Act empowers local authorities, in consultation with the Nature Conservancy, to create local Nature reserves. Little surprise will be expressed that to date very few authorities have taken such powers. One Scottish and two English county councils have, however, shown their practical interest, and it is not over-optimistic to expect that the number of such local reserves may increase steadily, if but slowly. No doubt the still existent framework of the old Nature Reserves Investigation Committee's county sub-committees can be of use here, in bringing to the attention of their local authorities habitats which require protection and for which the establishment of a local reserve may be feasible.

The wider functions of the Conservancy, namely, the provision of advice upon, and the promotion of research into, the conservation and control of natural populations, present a multitude of problems, not the least of which is our fundamental ignorance of the ecological factors which determine the status of even the commonest of our animals and plants. The science of ecology is still young, and the rate at which

its study yields comprehensive results must be slow, because of the nature of its material and of the intricacy of the complex of physical and biotic factors within which all living organisms exist. It seems, therefore, that the Nature Conservancy may for some years be at best a one-eyed adviser, except where problems relate to only the most simple factors. It is relevant to emphasize that in the case of each of the four examples quoted in the first report no adequate answer could be returned. In fact, the reply was virtually, "We do not know, but we will try to find out", and research has been initiated in an effort to discover the solution.

To biologists therefore, as indeed to all who are prepared to take an objective view of conservation, the most interesting and stimulating sections of these two reports are those announcing the establishment and organization of the Conservancy's own research stations, at Merlewood, with Moorhouse at its doorstep, at Anancum in the Beinn Eighe Reserve, and at Furzebrook in Dorset. Coupled with this must be Appendixes V, VI and VII to the second report, in which are listed the grants awarded to universities and other organizations for the development of research into specific field-problems. One of the strongest deterrents to the initiation of fundamental ecological research, particularly in relation to animal populations, has been the breadth of the task which must be faced. Even the so-called autecological study of the bionomics of a single species must involve the investigator in an infinitude of problems in which the physical factors of climate and micro-climate, geology and soil structure and physiography may be involved, while willy-nilly an extensive study of the lives and relationships of a greater or lesser number of other species must be examined in order to determine the nature of their influence upon the species in which the worker is primarily interested. He must therefore be equipped in some measure as meteorologist, pedologist, taxonomist and statistician, and in a host of other techniques. Few men and women are able to attain to this width of interests, and in practice aid is sought from other experts in the solution of the many problems which have to be examined.

Synecology—the study of whole habitats and of the total assemblages of plants and animals within them—presents a still greater complexity of pattern, and demands so high a degree of concentration, knowledge and labour that few investigations of this kind have been successfully concluded. Nevertheless, the autecology of any species cannot be elucidated without reference to the synecology of the habitat in which it lives. It follows, therefore, that the ultimate aim of ecological science must involve a detailed synecological picture of at least the major habitats of the world. Only then will it become possible to assess correctly the status of the individual species; and, from the point of view of human welfare, only then will it become possible to prophesy the consequences to be expected from any attempt to modify the status of a species, whether by encouragement, control or, in the final event, extermination.

It seems logical to expect that comprehensive ecological knowledge can only be attained through the work of teams of experts in groups of related fields; and it is therefore encouraging to observe the nucleus of one such team being created in the scientific staff of the Nature Conservancy. It is to be hoped that, once the organization has escaped its growing pains, its scientists will be freed from all

but the necessary minimum of administrative and advisory duties, in order that they may concentrate on research. Concurrently, the programme of assistance to universities and to reputable naturalist organizations is warmly welcome. There is a wealth of talent among amateur naturalists, about which they themselves are frequently unduly humble. The exact observer who is prepared to devote his leisure to the ordered study of an area, or of a group of animals or plants, can, and does, make as important contributions to biological knowledge as do many professional scientists. Indeed, the increased load of administrative and teaching duties which besets the university teacher is usually now so heavy as virtually to preclude him from spending sufficient time, at the right times, in the field. As a result, much of his ecological work must be done by proxy. It is here that the training and research grants made by the Conservancy to university departments are so important. Thus, not only is a continual stream of apprentice recruits provided, but also the experienced ecologist is enabled to stimulate and direct work for which he himself no longer has time or freedom.

In conclusion, it is relevant to refer to the 1947 report of the Wild Life Conservation Special Committee¹. This committee examined the problem which has been adumbrated in the foregoing paragraphs, and made a number of recommendations, of which the most stimulating was perhaps that mooted the idea of freedom of movement of members of staff between museums, the Nature Conservancy and university departments. The ecological worker would thereby gain a wide experience of different disciplines, techniques and methods of attack upon his problems. Such increased versatility is so patently desirable as to create the hope that the idea has not been pigeon-holed and forgotten.

RECENT ADVANCES IN ANIMAL MORPHOGENESIS

THE conference sponsored by the editorial board of the *Journal of Embryology and Experimental Morphology* and held in London during January 9-12 permitted a large number of biologists to hear and discuss accounts of recent work on many major aspects of animal morphogenesis. For this opportunity they were primarily indebted to their Continental colleagues, whose participation has provided an important stimulus to British interest in this field.

That rewarding work may still be found in the exploration of the classical problems of embryology was shown by Prof. J. Pasteels (Brussels), who described the first fruits of an investigation of embryonic stages of reptiles from the Belgian Congo. He has been able to show that the migration of the primordial germ cells to the gonadal ridges by a vascular route, long known in birds and *Sphenodon*, occurs also in lacertilians. A study of body form and brain morphology in species of different habits showed that relative functional importance in the adult can be anticipated by the embryo at a remarkably early stage. The brains of embryo

chameleons (animals which in the adult rely largely upon their visual sense) and those of the embryo *Mabuia* (in the adult largely olfactory) show early differences in the size of optic and olfactory centres. Similar considerations seem to govern the form of the body generally and of the limb, both of which in adult lacertilians may show wide differences in form and function.

Although the general configuration of the embryo can show a precocious anticipation of the functional adaptations of the adult, things are not necessarily the same at the histological level. Prof. A. Stefanelli (Rome) described cells within the optic tectum of teleost fishes which are bipolar in form and possess a recurrent branch arising from the outer fibre. To see how far their differentiation was dependent upon function, studies were made of their development in oviparous fish; in viviparous fish, in which animals before and after birth were compared; and in blind cave fish compared with related forms with vision. Blind fish, in which the eyeball is normally nearly completely enclosed in a bony capsule and in which there is no functional optic nerve, may nevertheless possess some of these neurones with their major features intact. Blindness in this species seems to have led to a reduction in the number of neurones subserving vision without altering the general features of the histogenesis of those surviving.

Prof. F. E. Lehmann (Berne) has made an electron microscope study of the cytoplasmic constituents of blastomeres of known morphogenetic properties from the eggs of the oligohaste *Tubifex* and of the sea-urchin. The technical problems of preparing the material have been overcome by treatment with glycerine or sucrose, which makes the cells brittle and easy to isolate from the germ and also dehydrates them sufficiently to inhibit autolysis. Fixation by osmium tetroxide provides good preservation of mitochondria, but a more acid fixative is required for the study of microsomes. The cells studied in the *Tubifex* germ were the somatoblasts 2d and 4d, the first giving rise to ectoderm and the latter to mesoblast in normogenesis. The cytoplasm of these cells was shown to differ in the density of the population of mitochondria—4d having many more than 2d—and in the nature and numbers of smaller inclusions. The microsome populations of different cells in the sea-urchin blastula also showed characteristic differences. In the micromeres are found many small microsomes, while there is a gradient in the concentration of mitochondria from animal to vegetal pole with a maximum at the animal pole.

Prof. Chr. P. Raven (Utrecht) gave an account of the effects of lithium ions on the development of *Limnaea stagnalis*, and of some ways in which these effects could be modified. Treatment with lithium chloride may induce exogastrulation and cyclocephalic malformations—in extreme cases cyclopia itself. These two effects are, however, independent, and it is suggested that the effect of lithium is both to weaken an animal field and to disturb the vegetal pole material. There is evidence that exogastrulation and cyclopia are independent consequences of a causal chain in which the lithium has a primary effect mediating a secondary disturbance of the respiratory processes which is responsible for the observed tertiary effects. Combinations of other ions with lithium show that while potassium, if anything, increases the lithium effect, either calcium or potassium cyanide may exercise a protective function. Conditions of oxygen lack, which in themselves induce

exogastrulation, are not so effective in presence of lithium ions. Concentrated potassium cyanide and heat shocks may both imitate the lithium effect. Dilute potassium cyanide under conditions of anaerobiosis increases the effectiveness of the latter as an agent causing exogastrulation. Exogastrulation, but not cyclopia, can be produced by centrifugation.

The mammalian egg, still largely inaccessible to the surgical procedures used on lower vertebrates, is coming to assume its rightful place in contemporary embryological advance by the application to it of the methods of cytochemistry, and Prof. A. Daloq (Brussels) showed how great the recent increase in our knowledge of its biochemistry has been. Studies on mitochondria and other visible particles in the maturing oocyte during fertilization and the early stages of development have been combined with examinations of the distribution of nucleic acids, polysaccharides and alkaline phosphatase. During oogenesis the most important changes seem to concern the microsomes and larger visible granules, these being active in the synthesis of cytoplasm and metaplasmic inclusions. Nuclear extrusions are also important at this stage. Fertilization sees little change in the visible cytoplasmic particles; but nuclear activation is accompanied by a temporary reduction in the deoxyribonucleic acid of both sperm and oocyte nuclei. The deoxyribonucleic acid is, however, rapidly recovered as the pronuclei form. Early development sees the first appearance of alkaline phosphatase. Bilateral symmetry, already apparent in the distribution of cell constituents in the maturing oocyte, becomes marked in the later cleavage stages, and from this time onward differences in the cytoplasmic constitution of cells with different fates become apparent. To some extent it is already possible to explain the biochemical activity of these cells in terms of their capacity for performing certain morphogenetic functions.

Prof. S. Hörstadius (Uppsala) described a further analysis of the organization of the young sea-urchin germ. The reduction of Janus green in cells under conditions of diminishing oxygen tension can be used to distinguish between regions of the egg with high and those with low metabolic activity. In such conditions a normal egg will show reduction (that is, high metabolic activity) first at the vegetal pole, then in the apical region and last of all in the region of the ciliary band. Isolated animal and vegetal halves in these conditions display simultaneous onset of Janus green reduction, and this indicates that the vegetal region normally inhibits the apical one. Micromeres implanted into the side of the animal hemisphere induce a reduction centre there, and are also effective in distorting the gradient in mitochondrial density that runs from animal to vegetal poles. Work with anti-metabolites had revealed a rather surprising phenomenon, since while 8-chloroxanthene (blocking purine and nucleic acid metabolism) had an animalizing effect and phenyllactic acid (blocking amino-acid metabolism) had a vegetalizing effect, both gave rise to a number of peculiar radially symmetrical larvae of a kind that Gustafson had produced with detergents. Both substances were, in fact, acting in this way, though it is open to question how far this is relevant to their other morphogenetic effects.

In the classical experiments on neural induction in the urodele embryo the structures induced were either ectodermal in nature or associated with ectodermal inductions. It has now proved possible to

induce structures of wholly, or almost wholly, mesodermal nature. Prof. S. Toivonen (Helsinki) reported a study of inductions produced by alcohol-treated guinea-pig bone marrow after its implantation into the gastrula or when placed in ectodermal 'sandwich' explants. It is noteworthy that the tissues induced in such experiments are those which in normogenesis would arise from both endomesoderm and ectomesoderm. Secondary inductions sometimes, but by no means always, occur. The same inductor if further treated with hot water for a short period undergoes a remarkable change in properties. It now induces only structures arising in normogenesis from the ectoderm, for example, lenses and balancers, though rarely, if ever, neural cells. Prof. Toivonen believes that this change is not due to a transformation of the mesoderm inductor but results from its complete destruction, with the consequent unmasking of an ectodermal inductor that had previously been unable to express itself.

Prof. J. Brachet (Brussels) described a technique for the autoradiographic localization of labelled atoms developed in his laboratory by Mme. A. Fioq. It uses the thick emulsions prepared for the study of cosmic radiation. The method permits of the location of labelled atoms with a resolution of about 1 micron. Experiments on the oocytes of *Asterias* using marked glycine showed that the activity of the nucleolus was nearly a hundred times as great as that of either nuclear sap or cytoplasm after one hour's treatment. When applied to the process of embryonic induction the method revealed that when either labelled glycine or orotic acid is incorporated into an amphibian organizer that is then implanted into another gastrula, radioactivity can later be detected not only in the secondary neural tube but also, to a lesser extent, in the host's normal nervous system. The method can also be used to identify lithium if the preparations are subjected to neutron bombardment which splits the lithium atoms. It has been possible in this way to demonstrate a distinct accumulation of lithium in the dorsal half of amphibian gastrulae formed from eggs treated with 1 per cent lithium chloride.

Prof. O. H. Waddington (Edinburgh) reported the methods being developed in his laboratory using radioactive amino-acids and the stripping film method in the study of embryonic processes in amphibians and birds. Using radioactive methionine and glycine, it had proved possible to get usable concentrations in axolotl and *Xenopus* embryos, and radioactive methionine could successfully be introduced into chick embryos by injecting the albumen in the neighbourhood of the blastoderm and maintaining the egg at room temperature for 12-24 hr. Preliminary results suggested that significant differences in the subsequent radioactivity of different organ rudiments could be detected.

From Prof. Waddington's laboratory there also came a film, exhibited by Dr. D. A. Ede, of the development of *Drosophila*. A surprising amount of the morphogenetic activity from fertilization onwards can be seen by time-lapse cinematography of the whole egg, and shots of eggs doomed to early death by their genetic constitution showed that the method holds great promise for the study of abnormal development.

For workers on the Protozoa, cell division does not serve morphogenetic processes so much as itself set the scene in which morphogenetic processes must necessarily play their part. Prof. E. Fauré-Fremiet

(Paris) described some of the processes which accompany the division of the ciliate *Urocentrum turbo* into an anterior individual or proter and a posterior one or opisthe. In this species the kinetosomes of the meridional kineties are so arranged as to lie in circular transverse lines ending in an anterior belt or fascia and an equatorial singula. At the onset of division the singula widens by the multiplication of its kinetosomes. It is thus a morphogenetic zone corresponding to Oalkin's division zone. The singular kinetosomes then become distributed along the meridional somatic kineties to complete the morphogenesis of the anterior part of the opisthe and the posterior part of the proter. The oral ciliation presents an autonomous system with its own morphogenetic zone.

Prof. E. C. Wolff (Strasbourg) described the progress made in his laboratory in the attempt to replace chick embryo extract by known mixtures of amino-acids as a medium permitting the survival, differentiation and growth of rudimentary organs *in vitro*. Using the syrinxes, tibias or the gonads taken from bird embryos of 7-9 days incubation as explants, media composed of agar, glucose and saline to which amino-acids and vitamins had been added were tested for their power to sustain growth and differentiation over a seven-day culture period. Growth in the explants was judged by the presence of mitoses and more particularly by the increase in total nitrogen. Marked growth and differentiation in media containing many amino-acids had been obtained; but when an attempt was made to find the minimum requirements of amino-acids for the explants it was discovered that though growth can occur in media to which only a few had been added, the requirements of different organ-rudiments are not the same.

Mr. M. Abercrombie (London) described observations on chick heart fibroblasts in tissue culture which had suggested that 'contact inhibition' was an important factor determining the behaviour of the individual cells and some of the properties of the whole culture. By 'contact inhibition' is meant inhibition of movement, in directions normal to the plane of contact, in two contiguous cells. The evidence for the existence of this phenomenon comes mainly from the behaviour of the outgrowths from two neighbouring explants at their zone of junction in a fluid medium. The failure of the outgrowths to 'overlap' or be thrown into folds bears striking testimony to the unwillingness of their cells to climb over one another. Contact inhibition is not only consistent with well-known features of fibroblast cultures, but may actually explain many of them. Interactions between outgrowths of explants from different organs, and even from different species, go to confirm the generality of the phenomenon, while the three-dimensional outgrowths from explants in plasma clots show it in conditions more nearly comparable with the situation in which fibroblasts occur in the organism.

A number of the papers were accompanied by demonstrations of research material, and in addition such material was presented by Dr. S. M. Manton and Mr. K. T. Anderson illustrating maternal-embryonal connexions in viviparous Onychophora, by Prof. P. B. Medawar, Dr. R. E. Billingham and Mr. L. Brent to illustrate the principle of actively acquired tolerance of foreign cells in mammals and birds, and by Dr. D. R. Newth on the behaviour of lamprey neural crest cells in homoplastic and xenoplastic transplantation.

Dr. R. A. Beatty, Dr. M. Fischberg, Dr. J. Needham, Dr. Muriel Robertson, Prof. J. Z. Young and a number of others contributed to the discussions on the papers read.

A most valuable discussion on the nature of inducing stimuli, led by Prof. J. Pasteels, was also held. It showed that interest in this subject is still high, and that the seemingly formidable difficulties that blocked the search for a single chemical or physical agent of neural induction have not prevented the accumulation of ever more precise information on the biology of the process.

The conference was made possible by the generosity of the Royal Society, the Ciba Foundation, the British Council and the Wellcome Foundation.

D. R. NEWTH

METALLIC TRANSFER IN SCREWING AND ITS SIGNIFICANCE IN BONE SURGERY

By DR. F. P. BOWDEN, F.R.S., and J. B. P. WILLIAMSON

Physics and Chemistry of Surfaces, Department of Physical Chemistry, University of Cambridge

and P. GOWANS LAING

The Royal Infirmary, Bradford

EARLIER experiments have shown that when two metals are placed in contact, appreciable metallic transfer occurs from one surface to the other. If sliding takes place, the amount of metal transferred is increased considerably. A general account of this work has been given elsewhere¹.

In simple mechanical operations such as screwing or bolting, we may expect that some transfer will occur between the screwdriver and the screw or the spanner and the bolt. Although the transfer will be small, it may under certain conditions be important. For example, in modern surgery it is customary to use metallic plates to strengthen or to repair a fractured bone. These are screwed or bolted on to the bone and may remain permanently in position. The plates, screws and bolts are all made from a stainless steel which has a very high corrosion resistance. Intensive investigations have been undertaken in recent years to select the best steel for this purpose. It has been found that steel of the specification shown in Table 1 (a) is one of the most inert when in contact with human tissues². It was also found that if metal alloys of differing compositions are placed in contact in the human body, metal corrosion and 'electrolytic inflammation' in the tissues occur³. 'Electrolytic inflammation' consists in the inflammatory cells of the tissues becoming more numerous and an increased local vascularity of bone and soft tissue. This condition interferes with the normal healing of bone and soft tissues and may eventually produce heavy scarring. Orthopaedic surgeons therefore take great care that all plates and screws which are to be left in contact are made of the same alloy. The insertion of 'mixed metals' is always avoided. These plates and screws are electrolytically polished and are passivated in nitric acid. Nevertheless, it is found in practice that inflammation and corrosion do occasionally occur.

Table 1

(a)	(b)
Specification for screws and plates (per cent by weight)	Specification for tools (per cent by weight)
Carbon 0.07	Carbon 0.17
Silicon 0.30	Silicon 0.24
Manganese 0.5	Manganese 0.5
Chromium 18.0	Chromium 12.6
Nickel 8.0	Nickel 0.34
Iron 70.25	Iron 85.43
Molybdenum 2.75	

The screwdrivers, spanners and forceps used in this form of bone surgery are also made from stainless steel, but of a composition differing from that of the plates (see Table 1 b) and are less resistant to corrosion.

If small fragments of this different steel are welded on to the screws during the screwing operation, they may, when immersed in the body tissue, form small electrolytic couples which cause inflammation and accelerate corrosion. Experiments were therefore carried out to investigate whether metallic transfer occurred and to determine its amount and distribution. Measurements showed that the steel for the tools was appreciably softer (V.P.H. 150) than the steel for the screws and plates (V.P.H. 380).

Experimental. The experiments consisted of driving the screws with a screwdriver having a radioactive tip, and then determining the amounts of metal transferred from the driver to the screw heads by measuring their acquired radioactivities. In order that the forces involved should approximate as closely as possible to those occurring in an actual operation, the screws were driven into bone. The experiment was carried out using samples of splints and self-tapping screws manufactured for medical use, and a splint was fastened by four screws to a leg bone taken from fresh beef. The screws were started by drilling a small hole in the bone with an electric hand-drill and were then driven home and tightened with a screwdriver. This driver had a normal handle and shank, but, instead of a tip, had a small hole recessed into its end. Into this hole a slab of metal $\frac{1}{8}$ in. $\times$ $\frac{1}{4}$ in. $\times$ $\frac{1}{8}$ in. cut from the tip of an actual medical screwdriver was inserted and used as the screwdriver tip.

Before the experiment, this slab was irradiated in the neutron pile at Harwell and acquired a radioactivity of about $\frac{1}{2}$ mc. For the present purpose only the activity of the chromium in the steel was significant. This consists of K-radiation and γ -radiation of 0.323 MeV. The screws and the driver were degassed with suitable solvents and the first screw was driven home firmly but carefully, so as not to cause appreciable slip between the driver and head. The driver slipped slightly in the slot while the second screw was being driven in; and two deliberate slips were made along the slot of the third screw. The fourth screw was driven and tightened with the utmost caution, and no slip was perceptible.

A Geiger counter was used for measuring the acquired activity of each head. Only γ -rays were counted. Thus any radiation emanating from transferred metal adhering to the bottom of the slot was not shielded by the mass of the screw head, and the entire amount of adherent metal was recorded.

Results. The specific strength of the radioactive metal was measured by counting the γ -emission from the slab used as the screwdriver tip, in the same Geiger counter under the same geometrical conditions; the weight of this slab having been determined before irradiation. In this way the mass of metal trans-

Fig. 1. Autoradiographs of radiation given off by transferred metal on screws. (a) 1st screw driven carefully, 22 μ gm. (b) 2nd screw, slight slip, 47 μ gm. (c) 3rd screw, greater slip, 65 μ gm. (d) 4th screw, extreme care, 17 μ gm. (e) 2nd screw; distribution of transferred metal within slot, the line is the edge of the film and the bottom of the slot. (f) Position of film for autoradiograph shown in e.

ferred from the driver to the screw head was calculated:

1st screw	22 μ gm.	3rd screw	65 μ gm.
2nd screw	47 μ gm.	4th screw	17 μ gm.

The distribution of the transferred metal was determined using an autoradiographic technique. In this method the radioactive particles were photographed by their own radiation on a sheet of X-ray photographic film placed against the screw head. The screws were placed head downwards on the film and the photographs shown in Fig. 1, a-d, were obtained. Each photograph shows a grey region caused by weak radiation emanating from transferred metal within the slot of the screw, while several small areas of intense whitening indicating transferred particles along the outer edges of the slots are visible in the photographs of the second and third screws.

A photograph showing the distribution of transferred metal within the slot was obtained by inserting the edge of a sheet of film into the slot of the second screw (see Fig. 1, e and f). This indicates only a little radiation emanating from the bottom of the slot, but shows several densely whitened areas corresponding to metal adhering to the outer edges of the slot.

Combining the information displayed in Fig. 1, it is possible to estimate that most of the transfer consists of a small number of discrete particles, each having a mass of a few micrograms. Most of the transferred metal is distributed along the outer edges of the slot of the screw (see Fig. 2). If more severe

conditions of screwing are used, we may expect the transfer to be correspondingly greater.

Some measurements were made of the electrode potential of these steels immersed in N/10 sodium chloride and in N/10 hydrochloric acid solutions, since this is

Fig. 2. Diagram of screw head, showing where adherent metal was detected.

a major factor in determining inflammation and corrosion. In each solution the steel of the driver was strongly electro-negative to that of the screw. This means that under these conditions the two steels could form an electrolytic couple with the driver steel acting as the anode. Samples of the two steels were left in the hydrochloric acid solution for two days. The screw steel showed no apparent corrosion, but the driver steel showed marked chemical attack.

Surgical observations. During operations on fractured bones which had previously been fixed with metal plates and screws, portions of the tissues in contact with the metal were removed for microscopic examination. Ten biopsy specimens were obtained. All ten specimens had been in contact with the metal for more than four months and none longer than ten months. No complicating sepsis had occurred in any of these cases. Two microtome sections were prepared from each specimen. One was stained with haematoxylin and eosin in order to demonstrate the presence of iron salts in the tissue. These salts are present only when there has been considerable inflammation.

The other was stained to detect the presence of smaller quantities of iron in and around the cells by the Prussian blue reaction. The presence of iron in the tissue indicates that corrosion has occurred. It is not in itself very harmful. It is the electrolytic reaction which interferes with the healing of the tissue.

Specimens of tissue removed from areas adjacent to the heads of the screws and bolts showed heavy iron infiltration and tissue inflammation (Fig. 3, b). Specimens removed from areas adjacent to metal surfaces which had not been handled heavily showed little iron infiltration or inflammation (Fig. 3, a). Over the period studied, the amount of inflammatory change and iron deposit did not depend markedly on the length of time the metal had been buried.

Conclusion. The presence of free iron in the tissues adjacent to the stainless steel is taken as evidence of corrosion of the metal. Such corrosion is accompanied by an 'electrolytic inflammation' which interferes with the bone union and healing. Consideration of the surgical material shows that an inert alloy can, on occasion, behave as a toxic one.

Fig. 3. Photomicrographs of microtome sections of tissue stained to show presence of iron. (a) Tissue adjacent to region of stainless steel plate which had not been handled; no iron present. (b) Tissue adjacent to region where heavy handling had occurred; heavy deposits of iron.

This occurs where the metal has been handled with screwdrivers or spanners, and is apparently more marked when the handling is severe. It is less marked when the metal has not been handled heavily.

The physical experiments show that it is almost impossible to insert a screw without leaving some fragments of metal from the driver adherent to the screw. The amount increases markedly if any slip occurs during screwing. The steel used for the plates and screws is very resistant to corrosion, but that used for the screwdrivers and spanners is not. Measurements show that an appreciable difference in electrode potential can be set up between these two steels, so that they form an electrolytic couple which may have a harmful effect on the healing of the tissue and which will act as a corrosion centre. These physical observations may therefore offer an explanation of the surgical behaviour. Other factors which may play a part are the plastic deformation of the steel and the deformation of the protective oxide layers since these can alter the electrode potential. The effect of differential transfer can be diminished by a suitable selection of the metal used both for the driver and for the screws. We find, for example, that if the screws are made of 'Vitalium' alloy the amount of the driver transferred to it is very much less.

Analogous experiments in bolting operations show that the amount of metal transferred from the spanner to the bolt head is greater than that observed in screwing.

We thank Down Bros. and Mayer and Phelps, Ltd., for gifts of medical tools and screws.

OBITUARY

Prof. E. P. Cathcart, C.B.E., F.R.S.

EDWARD PROVAN CATHCART, whose death occurred on February 18, retired in 1947 from the regius chair of physiology in the University of Glasgow after almost half a century of continuous devotion to the study of man as a whole; yet, shortly after he first graduated in medicine in 1900, he went to Germany to study bacteriology. There he came under the influence of Voit, whom he revered as a master. At the beginning of this century direct observations on human beings were largely confined to studies of metabolic processes. Such an approach appealed to Cathcart, and his appointment in 1905 to the newly founded Grieve lectureship in physiological chemistry in his own University gave his predilection full scope. In 1907 he published two classical papers on the metabolism of protein and of inorganic elements during starvation. He used Beauté, a *Hungerkünstler*, as subject. On himself he observed the influence of carbohydrate and of fat on protein metabolism.

Cathcart travelled widely; he studied in Russia with Pavlov, whose influence is shown in the publication of two papers on the gastro-intestinal tract of dogs. Cathcart never took kindly to work on lower animals; more to his liking was his work with Benedict in the United States on energy exchange in

man during muscular exercise. Their joint monograph, "Muscular Work", which appeared in 1913, is a classic.

In 1915 Cathcart was appointed to the University chair of physiology in the London Hospital. The First World War was not a period wholly of frustration. He put his special knowledge at the service of the Armed Forces and of the country, and out of this phase arose his abiding interest in nutrition, in human food habits and in the physique of men and women. A monograph on the energy expenditure of the infantry recruit in training was written in collaboration with Lord Boyd Orr and published by H.M. Stationary Office in 1919. Many papers on similar topics appeared in the *Journal of the Royal Army Medical Corps*.

In 1919 Cathcart was invited by his own University to become the first Gardiner professor of physiological chemistry. In 1921 appeared his "Physiology of Protein Metabolism", one of the famous series of "Biochemical Monographs". Cathcart still kept alive his interest in metabolism, paying special attention to the influence of muscular work. With Markowitz he wrote a most acute analysis of the significance of the respiratory quotient, being rather impatient with the oversimplified native interpretations then current. However, a shift in the emphasis of his work gradually became apparent. Between 1924 and 1940, the Medical Research Council published five of his reports on the diets of families in different parts of Britain. Membership of the Industrial Fatigue Research Board (later Industrial Health Research Board), of which he was to become chairman during 1933-40, led to work on human physique and stature and to the appearance of two monographs, one on the physique of women in industry (1927) and another on the physique of man in industry (1935).

In 1928 Cathcart succeeded Noel Paton in the regius chair of physiology in the University of Glasgow. In his later years committee work and administration made increasingly heavy demands on his time; his colleagues in the Physiological and Biochemical Societies saw progressively less of his spare dynamic figure. Yet he kept alive his interest in the implications of physiological knowledge for social welfare, he did some little work on psychology, and his last scientific publication in 1948 dealt with histological work on the innervation of the nipple.

Cathcart's work, in spite of its seeming diversity, was all of a piece. His early studies on metabolism, on the alimentary canal and on energy exchange in man led on smoothly to his later work with its wide social implications.

Without being reactionary, Cathcart had yet a sceptical habit of mind. The new and the novel in physiology and in social science had less appeal than the established facts and accepted attitudes of the past. Facts were naturally sacred; but comment, he felt, ought not to be too free in view of our essential ignorance of the functioning of the integrated organism as a whole. Thus Cathcart resisted what he regarded as excessive emphasis on the importance of vitamins and of 'minerals' in nutrition; 'nature' to him was as important, if not more important, than 'nurture'. Yet he was a most stimulating teacher, in his personal relations he was kindly and sympathetic, and he went to endless pains to encourage and to help young workers. It is to be doubted if we shall see again anyone so well versed in the broad principles of human biology.

R. C. GARRY

NEWS and VIEWS

Physical and Inorganic Chemistry at Bristol:

Prof. W. E. Garner, C.B.E., F.R.S.

PROF. W. E. GARNER is retiring after twenty-seven years from the Leverhulme chair of physical and inorganic chemistry in the University of Bristol, to which he was appointed in 1926, in succession to the late Prof. J. W. McBain. Prof. Garner's energy and outstanding ability have been devoted to the well-being of the Chemistry Department and research, and to the fostering of collaboration between different departments of the University and between his Department and industry. He created the inter-departmental honours school of biological chemistry in 1950. During the Second World War the resources of the Chemistry Department were marshalled for explosives research, and Prof. Garner whole-heartedly applied himself to national work, becoming temporarily, in 1944, chief superintendent of armaments research at Fort Halstead. His researches have been typically broad. He has made valuable contributions to the study of flames and of explosions in gases and solids. His pioneer work on nucleation and decomposition of azides and hydrates, and on the relations between the physical properties and the chain lengths of aliphatic compounds, is of fundamental importance. Work on the surface chemistry of solids, and on the heat and kinetics of adsorption, developed later into an intensive study of oxide catalysts. He was elected to the Royal Society in 1937, made president of the Faraday Society in 1946 and pro-vice-chancellor of the University of Bristol in 1952. Students and colleagues of Prof. Garner have all been inspired by his enthusiasm and insight, and he has always been approachable by even the most junior. Scrupulous fairness, talent for securing willing co-operation, and his ability to put first the real interests of others, have made his Department a most happy one.

Prof. D. H. Everett, M.B.E.

PROF. D. H. EVERETT, professor of chemistry since 1948 at University College, Dundee, in the University of St. Andrews, has been appointed to succeed Prof. W. E. Garner in the Leverhulme chair at Bristol. Prof. Everett received his scientific training in the University of Reading, and his first researches were done there and at Dundee under Prof. W. F. K. Wynne-Jones. In 1939 he went as a Ramsay Fellow to work on reaction kinetics under Mr. R. P. Bell at Balliol College, Oxford, but after a short time joined Sir Cyril Hinshelwood's research team working for the Ministry of Supply. From 1942 until the end of the War he was attached to the War Office and undertook scientific liaison missions to the Middle and Far East. Prof. Everett returned to Oxford as an Imperial Chemical Industries Fellow, and in 1947, after a short period as lecturer in Dundee, was elected to an official fellowship at Exeter College, Oxford. He was appointed to the chair in Dundee in 1948, and during the past six years he has supervised the extension and re-equipping of the Chemistry Department and has established a vigorous research school which is working on the thermodynamics of acid-base equilibria, the electrochemistry of non-aqueous solutions, reaction kinetics, the thermodynamics of adsorption, and the phenomenon of physico-chemical hysteresis. He has also translated and revised Prigogine and Defay's "Chemical Thermodynamics", which is to be published very shortly.

Geology Division of the Anglo-Iranian Oil Co., Ltd.:

Dr. G. M. Lees, F.R.S.

DR. G. M. LEES has retired from his appointment as chief geologist of the Anglo-Iranian Oil Co., Ltd. He had a distinguished record in the First World War with the Royal Flying Corps, winning the Military Cross and the Distinguished Flying Cross, and later served as an assistant political officer in Southern Kurdistan. He joined the Anglo-Iranian Company in 1921 and his early work lay in south-west Persia and Oman; he was awarded a doctorate of philosophy in the University of Vienna for his researches in Oman. He was appointed chief geologist to the Company in 1930 at the age of thirty-two and thereafter worked in many different parts of the world. It was a period of intensive exploration and development; in all this Dr. Lees played an important part, demonstrating remarkable geological knowledge and a shrewd appreciation of practical problems. It was he, too, who inspired the search for oil in Great Britain which led to the discovery and exploitation of oilfields in Nottinghamshire. In 1943 he was awarded the Bigsby Medal of the Geological Society of London and in 1948 was elected a Fellow of the Royal Society. He was president of the Geological Society in 1951 and 1952. It is noteworthy that in his presidential addresses, delivered with his customary skill in exposition, he was concerned with fundamental concepts in geology, bringing to bear upon them the knowledge and experience gained in many countries. His work has always shown the essential unity of pure and applied science.

Mr. P. T. Cox, M.B.E., and Mr. N. L. Falcon

FOLLOWING Dr. Lees's retirement, Mr. P. T. Cox has been appointed chief geologist and exploration manager of the Anglo-Iranian Oil Co., and Mr. N. L. Falcon manager of the Company's geological division. Mr. Cox is a graduate of Canterbury University College, Christchurch, New Zealand, and after a short period on the Geological Survey of that country joined the Anglo-Iranian Oil Co. in 1924. He has worked in many countries, notably Peru, Venezuela, Colombia and the Middle East. He made a special study under Prof. Douvillé in Paris of Foraminifera, so important in oilfield geology. He was associated with Dr. Lees in the search for oil in Great Britain, and joint author with him of a paper on the geological basis of that search. He served with the Royal Engineers during the Second World War and was made M.B.E. He returned to Persia after demobilization and became general manager of the Company's oilfields there in 1948.

Mr. Falcon joined the Anglo-Iranian Oil Co. in 1927 after graduation in the University of Cambridge. He served in Persia until 1936, undertaking extensive geological surveys as well as oilfield development. Later he took part in the exploration drilling programme in Great Britain and became increasingly interested in the applications of air photography to geology. He served in the Intelligence Corps during the Second World War, his duties including the study of air photographs, and he was awarded the United States Bronze Star. Since the War, he has been concerned with a wide range of geological problems in Great Britain, Europe and the Middle East. He is author or joint author of papers on various subjects such as gravity-alip phenomena in Persia and the results of geophysical surveys in England.

Einstein Award : Dr. R. P. Feynman

THE third Einstein Award was made on March 14, the seventy-fifth birthday of Prof. Albert Einstein, to Dr. Richard Phillips Feynman, of the California Institute of Technology. This Award, which was established in 1950 by the Lewis and Rosa Strauss Memorial Fund, consists of a gold medal and fifteen thousand dollars, and the recipient is selected by a committee at the Institute for Advanced Study, Princeton, where Prof. Einstein works. The two previous Awards have been made to Dr. Julian S. Schwinger, of Harvard University, and Dr. Kurt Godel, of the Institute for Advanced Study. Dr. Feynman, who is a graduate of the Massachusetts Institute of Technology, received his degree of Ph.D. from Princeton University in 1942 and was professor of physics in Cornell University during 1945-48. The main field of his research is quantum mechanics and, particularly, quantum electrodynamics. Both among the results and among the concepts in the latter field, some of the most important work developed during the past decade is due to him. In this respect, his treatment of quantum mechanics by the probability amplitude method, and the development of what is known as the Feynman diagram in accounting for possible particle transformations, are especially noteworthy.

Textile Institute : Awards

HONORARY fellowship of the Textile Institute has been conferred on Prof. S. C. Harland, George Harrison professor of botany in the University of Manchester. Prof. Harland, who is the eleventh recipient of this honour, the highest that the Institute can bestow, is responsible for many notable advances in the volume, quality and stability of cotton crops throughout the world as a result of his work in plant breeding and genetics in the Sudan, the West Indies, Brazil and Peru, as well as in Great Britain. Other awards of the Institute have been made as follows : *Institute Medal*, to Mr. W. Howarth (general manager, Muesgrave Spinning Co., Ltd.) and to Dr. C. S. Whewell (reader in textile finishing, University of Leeds) in recognition of distinguished service to the textile industry in general and to the Institute in particular ; *Service Medal* to Mr. J. O. H. Hurd (head of the Textile Department, Leicester College of Technology) for valuable services rendered to the Institute.

Chemical Technology In Edinburgh : New Chair and Department

APPROVAL of the promotion of ordinances for the foundation of a chair of chemical technology and for the institution of a new degree of bachelor of technological science (B.Sc. Technological) has been given by the University of Edinburgh. This decision, taken after consultation with the Heriot-Watt College, Edinburgh, marks the joint response of the University and the College to the urgent need for an increased supply of trained technologists. Both institutions are already making substantial contributions to the demand for training in applied science, and the proposed extension in what has come to be accepted as the fourth main branch of engineering industry is notably appropriate in view of local and national developments in the chemical industry. The new Department of Chemical Technology will be housed in the Heriot-Watt College, where ample provision for it has been made in the extension of the College premises now under con-

struction. The new professor, although occupying the University chair, will act as head of the new Department in the College. The University has agreed to transfer to the College all the equipment in its Sub-Department of Technical Chemistry. The joint arrangement proposed provides a scheme whereby the requirements for the training of University and College students in this field may be met without duplication of effort. It is proposed to make a joint appeal to the appropriate firms in Scotland and elsewhere for contributions towards the endowment of the chair and for suitable equipment to be used for teaching purposes.

New Chairs at the University of Nottingham

IN commemoration of the long and distinguished services of Lord and Lady Trent, the Boots Pure Drug Co., Ltd., has given to the University of Nottingham the sum of £100,000 for the endowment of two new professorial chairs to be known as the Lord Trent chair of pharmaceutical chemistry and the Lady Trent chair of chemical engineering. The announcement of this generous benefaction was made at a special meeting of the Court at which the University accepted with deep regret the resignation, necessitated by continued ill-health, of Lord Trent from the office of chancellor. Lord Trent became a member of the University College Council in 1923 and was later chairman and president. By the charter of incorporation of the University granted in 1948 he was created chancellor. Until his recent retirement he had been since 1931 chairman of the Boots Pure Drug Co., which in 1949 contributed £50,000 to the University's endowment appeal. The natural interest of the Company in the development of chemistry found its expression so long ago as 1921 when, as Sir Jesse Boot, the first Lord Trent, to whose munificence the University owes its principal buildings at University Park, endowed the Sir Jesse Boot chair of chemistry. In founding a chair of pharmaceutical chemistry the Company has indicated its desire to encourage the study of pharmacy and the development of research. The endowment of a chair of chemical engineering, following the recent institution of the Cripps chairs of metallurgy and of production engineering (*Nature*, December 19, p. 1129), will materially aid the University in its plans for the further development of the technological sciences.

Year Book of the Royal Society

THE recently issued Royal Society "Year Book" (pp. 311 ; from the Royal Society, Burlington House, London, W.1 ; 1954 ; 15s.), like its predecessors, is a volume which, apart from its usefulness as a work of reference, is a book to be dipped into for the host of scientific items—some important and some less so, but all interesting enough—which are to be found among its pages. The lists of Fellows and foreign members occupy the first fifty pages and give their appointments, postal addresses, year of election to the Society, awards by the Society and service, if any, on the Council. It is interesting to note from these lists that there are four Fellows who were elected more than fifty years ago. The remaining five-sixths of the book is so full of miscellaneous information regarding the membership of the many types of committee and board, standing orders, procedure for the council, medal awards, lectures, financial trusts and funds, special fellowships and appointments, that even the listing of these items is a lengthy affair. One revealing

point emerges from these pages, namely, the way in which the Society is advised on the various branches of science by means of its sectional committees. These are eight in number and are as follows: mathematics; physics; chemistry; engineering sciences; geology; botany; zoology; and physiology and medical sciences. The first six have nine members each and the last two twelve. It is worth noting that the full title of the Royal Society is the Royal Society of London, for Improving Natural Knowledge. The fact that it exists for improving natural knowledge is a *sine qua non*; the "of London" would seem to-day to be merely significant of the *venue* of its meetings, for the Society is the premier national scientific body, being open to all members of the British Commonwealth and the Republic of Ireland.

The Piltown Flints

At a meeting of the Geological Society held at Burlington House on February 24, Mr. A. T. Marston exhibited a number of flints which he had attempted to stain with chromic acid or potassium dichromate in order to assist appreciation of the condition of the Piltown flint recently described by Drs. Oakley and Weiner (*Nature*, December 12, 1953). Mr. Marston pointed out that though some of these flints would not stain at all, others became deeply stained. In the latter case, however, the stain was very difficult to remove. As the stain on the Piltown flint had apparently been easily removed by acid, Mr. Marston queried whether it had indeed been artificially produced, and also inquired whether there was any possibility that traces of chromium might exist naturally in the ferruginous Piltown gravels. Dr. Oakley then exhibited specimens of flint from Piltown, and described tests that had been made on all the flints illustrated in the original paper by C. Dawson and A. Smith Woodward. All these flints had a ferruginous stain which was easily removed by acid, in contrast to other "natural" flints from the Piltown area collected at the same time, which had a heavy ferruginous stain that was not removed by acid. In one of the flints illustrated in the original paper (B.M.(N.H.) E. 606), the presence of chromium had also been demonstrated. Dr. Oakley believed that the illustrated flints had been stained artificially with a ferruginous solution, and in one case a chromic solution had also been used in order to make the flint less red, and so resemble more closely the "natural" flints.

New Journal of the Medical Faculty of Zagreb

A new and attractively produced journal entitled *Radovi Medicinskog Fakulteta u Zagrebu* (Vol. 1, pp. 146+7 plates; 1953) has been started by the Medical Faculty of Zagreb, under the direction of Prof. F. Kogoj. It contains articles on a variety of subjects, most of which have summaries in English or French. Drs. B. Gušić and Z. Kraljina write on otitis of suckling infants, and Dr. B. Milojević on his experience of the treatment of chronic suppurative otitis media by the endaural approach to the middle ear, an operation for which it is claimed that it shortens the period spent in hospital and makes possible direct approach to the middle ear cavity; so that the structures of this part of the ear are preserved and most cases recover their hearing. Drs. Lj. Bežović and L. Rabadžija discuss the reactions of the eosinophil blood cells in rats adapted to adrenalin and histamine, and Drs. J. Vesenjak-Zmijanac and V. Beličević report on influenza in

Zagreb during 1950-51. Dr. N. Allegretti considers the function of the insular apparatus and insulin in relation to the anterior lobe of the pituitary gland, the thyroid and the adrenal cortex, and Drs. E. Rosenzweig and F. Zernsky discuss about eighty-eight cases of brow-presentations at birth. An article by Dr. V. Bezjak on the classification of fungi isolated from man in Zagreb is the first report on these organisms in Yugoslavia. The early diagnosis and modern therapy of malignant tumours of the upper jaw and nose is discussed by Drs. B. Pegan and M. Špoljar; Dr. A. Brnobić writes on the etiology of two cases of professional allergic eczema, one caused by silkworm larvae, and Dr. Z. Jurin-Mratović on the treatment with penicillin of seventeen cases of scleroderma and chronic acrodermatitis. The good wishes of medical men will readily go to this promising new journal. The language difficulty will probably restrict its usefulness in Britain; but the English and French summaries give the gist of the articles, and those who wish to read them in full can probably arrange to have them translated.

Society for the Bibliography of Natural History

THE annual general meeting of the Society for the Bibliography of Natural History was held at the Geological Museum, London, S.W.7, on March 4. Mr. V. A. Eyles addressed the meeting on "Bibliography and the History of Science". The first part of the third volume of the Society's *Journal* was issued at the end of December 1953, containing ten articles, of which one is an appreciation of the late Dr. C. Davies Sharborn, first president of the Society. The following were elected officers of the Society: *President*, Dr. J. Ramsbottom; *Hon. Secretary and Treasurer*, Mr. A. O. Townsend, British Museum (Natural History), London, S.W.7; *Management Committee*, A. G. Davis, W. N. Edwards, F. C. Fraser, F. J. Griffin, W. T. Stearn, C. Kirke Swann.

Physical Society Exhibition

THE Physical Society's thirty-eighth Annual Exhibition of Scientific Instruments and Apparatus will be held in the Imperial College of Science and Technology, South Kensington, London, S.W.7, on the following dates: April 8, 9 and 12, 10 a.m.-8 p.m.; and April 10 and 13, 10 a.m.-5 p.m. The morning of April 8 (10 a.m.-2 p.m.) will be reserved for Fellows of the Society and the press only. This year the Exhibition is confined to the main building of the College, Imperial Institute Road. Three discourses (each at 6.15 p.m.) will be given as follows: April 8, "Electrical Contacts", by Prof. F. Llewellyn Jones; April 9, "An Artificial Talking Device", by Mr. W. Lawrence; and April 12, "The Study of Surface Micro-topography by Optical Methods", by Prof. S. Tolansky. Orders for the usual "Handbook" (6s., or 7s. 3d. by post) and all matters relating to the Exhibition should be addressed to the Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7.

Society for Analytical Chemistry

THE eightieth annual general meeting of the Society for Analytical Chemistry was held on March 3 in London, when the financial statement and report of the Council for the past year were submitted and approved. The membership of the Society was reported as being 1,646, an increase of 54 since last year. In addition to the eight ordinary meetings of the Society (six in London and one each in Glasgow

and Southampton), eighteen meetings were held by its Sections and Groups during the course of the year. At the conclusion of the meeting, the Bernard Dyer Memorial Lecture of the Society was given by Dr. E. B. Hughes, who spoke on "The Contribution of Public Analysts and Other Analytical Chemists to Public Welfare". The following officers and members of council were elected for the forthcoming year: *President*, D. W. Kent-Jones; *Past Presidents serving on the Council*, Lewis Rynon, G. W. Monier-Williams, J. R. Nicholls and G. Taylor; *Vice-Presidents*, O. A. Adams, A. J. Amos and T. McLaughlan; *Honorary Treasurer*, J. Hamenoe; *Honorary Secretary*, K. A. Williams; *Other Members of Council*, D. C. M. Adamson, A. L. Bacharach, R. O. Chirnside, Miss M. Corner, D. O. Garratt, J. Haslam, C. L. Hinton, H. W. Hodgson, H. M. N. H. Irving, A. G. J. Lipscomb, R. E. Stuckey and O. Whalley; *Ex-Officio Members*, T. W. Lovett (chairman of the North of England Section), R. S. Watson (chairman of the Scottish Section), A. M. Ward (chairman of the Microchemistry Group), A. A. Smales (chairman of the Physical Methods Group) and L. J. Harris (chairman of the Biological Methods Group); *Honorary Assistant Secretary*, N. L. Allport.

Garth Field Studies Centre

THE Garth Memorial Youth Hostel and Field Studies Centre (by Aberfeldy, Perthshire) is situated among fine Scottish mountain scenery and countryside which give excellent opportunities for work in zoology, botany, geology, geography and archaeology. Certain rooms in Garth House are occupied by the Scottish Field Studies Association, among which are a library-lecture room and a small laboratory. Accommodation is available for individuals and for parties up to 30-40. This year, the warden (Mr. F. N. Haynes) will conduct two courses on the botany of the area (July 10-17 and 24-31). Further information can be obtained from the Joint Honorary Secretary, Scottish Field Studies Association, Department of Botany, The University, Glasgow, W.2.

University Visitors to Great Britain

THE Association of Universities of the British Commonwealth (5 Gordon Square, London, W.C.1) publishes a list of "Academic Visitors to the United Kingdom", based principally on information furnished by the registrars of member universities and university colleges in overseas parts of the British Commonwealth. Copies are circulated to universities, learned societies and other interested bodies in the United Kingdom with the view of assisting them, if so desiring, to make contact with current or prospective visitors. Copies can be obtained on request. The list, which gives the name, university and post for each entry, is divided into two parts: visitors already in Britain, with approximate date of departure; and non-professional staff of Colonial Institutions spending their long vacation in Britain, with approximate dates.

Announcements

SIR ALEXANDER FLEMING, emeritus professor of bacteriology in the University of London, has been elected a foreign associate of the Paris Academy of Sciences in succession to the late Prof. M. Lugeon. Prof. Léopold Escande, professor of the mechanics of fluids in the University of Toulouse, has been elected a non-resident member of the Academy in

succession to the late Prof. E. Bataillon. Prof. Gabriel Foëx, professor of experimental physics in the University of Strasbourg, has been elected *correspondant* for the General Physics Section in succession to Prof. L. Néel, recently elected a non-resident member.

MR. A. G. PHACOCK, secretary of the Scientific Instrument Manufacturers' Association, has resigned and joined the board of Mervyn Instruments, St. John's, Woking, Surrey. He is well known as the honorary exhibition secretary of the Physical Society.

PROF. RAGNAR GRANIT, director of the Nobel Institute for Medicine, Stockholm, will give the Silliman Lectures this year, his subject being "Receptors and Sensory Perception". The Lectures, which are open to all those interested in neurophysiology, psychology, psychiatry and related fields, will be given in Yale University on April 29 and 30 and May 3, 4, 5, 6 and 7. They mark the fiftieth anniversary of the first Silliman Lectures on "The Integrative Action of the Nervous System", given in 1904 by the late Sir Charles Sherrington.

COMMONWEALTH Fund fellowships for members of the United Kingdom Home Civil Service to study in the United States during 1954-55 have been awarded to the following: A. Currall (Ministry of Materials), D. W. Davies (Department of Scientific and Industrial Research) and L. E. J. Roberts (Atomic Energy Research Establishment). Similar fellowships for those in the Colonial Civil Service have been awarded to A. L. C. Thorne (Nigeria) and K. J. Henderson (Federation of Malaya).

THE Chemical Society is offering a Corday-Morgan Award for 1953, consisting of a silver medal and a monetary prize (150 guineas), which will be made to the British chemist who published during 1953 the most meritorious contribution to experimental chemistry, and who, at the date of publication, had not attained the age of thirty-six years. Applications or recommendations in respect of the Award must be received not later than December 31, 1954. Further information can be obtained from the General Secretary of the Society, Burlington House, London, W.1.

THE Colorado School of Mines, Golden, Colorado, is offering a tuition scholarship to a male student from England for the academic year 1954-55. The scholarship, which is renewable for a maximum period of four years, carries exemption from tuition fees (about 425-475 dollars a year) but does not cover student's fee or personal expenses (about 80-110 dollars a month). Further particulars may be obtained from the Cultural Affairs Officer, American Embassy, 41 Grosvenor Square, London, W.1, or from the Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1. Applications must be sent to the latter by May 1.

As part of the Tenth International Congress of Agricultural and Food Industries, to be held in Madrid during May 30-June 6 (see *Nature*, February 20, p. 389), the International Federation of Fruit Juice Producers is holding its third international congress, which will take place during June 1-2. Persons in Great Britain who wish to attend should write to the Apple Juice Producers Association of Great Britain, 8-9 North End, Wisbech, Cambs, from which further information can be obtained.

DEEP-SEA RESEARCH

SEVEN papers, a foreword and a brief note on a symposium held in the Jane Hardman Geology Laboratories of the University of Liverpool during September 1-2, 1953, constitute the first number of a new scientific quarterly journal, *Deep-Sea Research**, sponsored by the Joint Committee on Oceanography of the International Council of Scientific Unions. All contributions deal essentially with the floor of the oceans, in accordance with the terms of reference of the sponsoring body, namely, "that its work should be restricted to the investigation of the deep-sea floor". The title of the journal tends, therefore, to be misleading, especially if, as seems to be indicated, its policy is to remain focused on deep-sea floor problems and research, the emphasis being mainly geological rather than oceanographical except by contingency. A title such as "Deep-Sea Floor Research" would thus appear more accurately to express the substance and intention of the journal, and would be more likely to attract those, besides oceanographers, to whom its contents would be of greatest concern and interest.

In the first article, on "International Collaboration in Deep-Sea Research", Dr. J. D. H. Wiseman (London), president of the Joint Commission on Oceanography, cites the complexity of the problems to be solved, together with the high cost of equipping and maintaining oceanic research expeditions, as the case for the practical necessity of international collaboration in such work, an essential prerequisite of which are accurate bathymetric charts of the sea-bed. Those produced by the International Hydrographic Bureau, Monaco, and collectively styled "General Bathymetric Chart of the Oceans", are commended provided they can be re-edited every five years. Dr. Wiseman suggests that if these charts were more widely known for their artistic and other qualities, not only among scientific workers, but also to librarians and shipping companies, they would soon become largely self-supporting. The paper further deals with recent scientific developments in deep-sea floor research; for example, the invention by Dr. B. Kullenberg (Sweden) of a new long-core (20 m.) bottom sampler¹, enabling the acquisition of unrivalled material for the study of historic and also pre-historic climatic changes; the evolution by Belgian and Swedish scientists, working in collaboration, of a new method for determining the rate of sedimentation on the sea floor; the rapid improvement in our knowledge of submarine topographical features by the aggregate efforts of a number of American submarine geologists working in conjunction with the United States Navy and Coast and Geodetic surveyors; the accurate measurement of the rate of heat-flow through the deep-sea floor by a co-operative effort of British and American scientific workers; and a number more. Of such promise, indeed, to the Joint Commission on Oceanography is the prospect of realization within a reasonable time of "a new level of understanding of deep-sea problems", consequent upon developments in electronics, physics, chemistry, methods of detailed surveying and sampling of the deep-sea floor; and recognising the virtual necessity of international collaboration in investigations to that end, Dr. Wiseman gives it as the express intention of the Commission to explore the possibility of

establishing a permanent, non-governmental bureau or council to act as an advisory and promoting organisation for the conduct of deep-sea floor and contingent investigations. In this, one may be disposed to be sceptical of the necessity to establish yet another body, especially a permanent one, for purposes which perhaps a judicious modification or extension of the terms of reference of existing organizations, national or other, might well and sufficiently include.

A second paper, by Dr. Wiseman and Mr. C. D. Ovey, the secretary of the above-mentioned Joint Commission, usefully sets out a list of approved and defined terms, with a statement of agreed principles to govern nomenclature, which it is proposed should be applied to deep-sea topographical features. Some of the terms, such as 'continental borderland', 'borderland slope', 'seascarp', 'seahigh', 'seamount', 'tablemount', 'seapeak' and 'seaknoll' are new; and the list, which is largely the work of the British National Committee on the Nomenclature of Ocean Bottom Features, set up under the corresponding International Committee of the International Association of Physical Oceanography, is now published in order to test the degree of universal acceptance and employment of the terms before the parent Committee promulgates its decisions. These terms, if universally approved and adopted, would, by the introduction of systematic nomenclature on the lines proposed, obviate much future confusion and ambiguity in the specification of oceanic bathymetric features.

Prof. Hans Pettersson (Sweden), in a third paper, gives a summary account of the origin, aims and principal results of "The Swedish Deep-Sea Expedition, 1947-48", which he was chiefly instrumental in instigating and carrying through to a successful conclusion. The main work of this fifteen-month circumnavigating enterprise on the 1,450-ton motor-schooner *Albatross*, loaned by the shipping firm of Broström and Co., Gothenburg, before being put into service as a training-ship, centred around Kullenberg's long-core bottom sampler operated at great depths, the record depth at which a long core was taken being 7,500 m. Bottom profile records to more than 7,000 m. were also made, revealing that, in these abyssal regions, as in lesser depths, 'flat areas of practically uniform soundings are the exception rather than the rule. As Prof. Pettersson points out, this new fact raises important questions regarding the dynamics, tectonic and volcanic, of the deep-sea floor, and implies replacement of the former conception of a vast sea-floor peneplain due to age-long uninterrupted sedimentation smoothing out any original ruggedness in the rocky substratum, by that of a constant 'resculpturing' of the ocean bed, producing abrupt differences in level. New techniques, methods and means, some of them devised during, and by members of, the expedition, were employed in the measurement of the thickness of the bottom sediment, in determining bottom water movements in very deep water by study of its optical properties and the prevalence and stratification of suspended particles, and in the taking of undisturbed water samples quite near to the bottom. Large quantities of water were collected and preserved for uranium and radium measurements, and trawling operations were carried out at great depths in the North Atlantic Ocean to study the abyssal fauna. It is hoped that

* *Deep-Sea Research*, 1, No. 1, October 1953. Pp. 64. (Published quarterly by the Pergamon Press, Ltd., 243 Marylebone Road, London, N.W.1.) 34 4s. a vol. or 24s. a number.

at least the essential scientific results of the expedition, some of which have already appeared, will be published before the end of 1956.

The next paper is a contribution by B. C. Heezen, M. Ewing and E. T. Miller, of the Lamont Geological Observatory of Columbia University, New York, and deals with a "Trans-Atlantic Profile of Total Magnetic Intensity and Topography, from Dakar to Barbados". Early flights over marine areas with an airborne magnetometer indicated that correlation might exist between topographical features and the character of the magnetic field. By enclosing this instrument in a non-magnetic, streamlined, water-proof case, and towing it behind a ship, magnetic surveys of oceanic areas have become possible without the use of specially constructed, non-magnetic vessels, and the above authors give an account of such a survey across the Atlantic in 1948, when west of Dakar for 170 miles the magnetic field was found to be smooth with anomalies of less than 25 gammas. Anomalies of 50 to more than 200 gammas, 5-40 nautical miles in width, were encountered from the Cape Verde Islands region to Barbados. The topographical contrast between the deep ocean basins and the Mid-Atlantic Ridge was not reflected in the anomaly curve, while large anomalies observed over the submerged parts of the Cape Verde Islands showed the effect of known volcanic islands. No such anomaly was observed near Barbados, or over the continental margin of Africa.

A paper follows by F. Bernard on the role of calcareous flagellates in deep-sea fertility and sedimentation, as shown by recent work in the Atlantic Ocean and in the Western Mediterranean. Coccolithophorids were found to be the chief subscribers to sedimentation to depths of at least 4,000 m., the total volume of calcareous flagellates generally amounting to more than 50 per cent, and often 95 per cent, of the phytoplankton in the bathypelagic zone.

Dr. Wiseman and N. Hendry, from a unique bottom sample collected by H.M.S. *Challenger* in 1951, write on the significance and diatom content of a deep-sea floor sample from the neighbourhood of the greatest oceanic depth. The sample was from a depth of about 10,505 m. at a position about five miles from the greatest known oceanic depth in the Marianas Trench* and was taken by means of a Baillie rod. The position was about 60 nautical miles west of that at which, during her classical voyage of 1872-76, the former H.M.S. *Challenger* took a similar sample in about 8,185 m. The two samples were similar in colour and of proportionately the same amounts of organically produced silica; but differed in the proportions of the organisms present, the earlier material being almost entirely composed of radiolarians with few diatom fragments, while approximately 4 per cent of the recent sample consisted essentially of diatoms with minor amounts of radiolaria. There was clear evidence of erosion, the authors state, in electron microscope photographs of the 1951 sample. In conclusion of this article, the geomorphological relations and some of the problems of deep-sea trenches are discussed.

The concluding article to this interesting number of the new journal is one giving further notes on the greatest oceanic sounding and the topography of the Marianas Trench, by Dr. T. F. Gaskell, J. C. Swallow and Commander G. S. Ritchie. J. B. TAIT

THE TRAVELLING SCHOLAR IN EUROPE

BRITISH COUNCIL ACTIVITIES

THE report which the British Council has issued*, with a foreword by Sir David Hughes Parry, on a co-operative experiment in academic interchange between the universities of the United Kingdom and those of certain other European countries is a fitting complement, alike to the recent report on the Fulbright Programme (see *Nature*, 173, 1; 1954) and to the discussions on academic interchange within the British Commonwealth at the Congress of Universities of the British Commonwealth last July. The experiment began as the product of a cultural convention in 1946 between the Governments of the United Kingdom and of Belgium, and the British Council was designated as the principal agent of the British Government in the joint administration of the mixed commissions established to further the aims of this and similar conventions concluded between the United Kingdom and seven other European countries. The British Council entrusted its responsibility for carrying out recommendations regarding university interchange to its Universities Advisory Committee, with Sir James Mountford as chairman; but in 1950 a special standing committee, under the chairmanship of Sir David Hughes Parry, the vice-chancellor of the University of London, was constituted to deal with proposals for foreign university interchange.

As a result of discussions with representatives of universities and education authorities in seven European countries, it became clear that there was a widespread demand throughout Europe for the re-establishment and increase of academic contacts with the United Kingdom, and that two main types of visit were required: the short visit of a few days to a week to enable scholar to meet scholar for the exchange of ideas, to give one or two formal lectures or to participate in colloquia; and the longer teaching visit of up to a term in length. More recently, Belgium has voiced a desire for the interchange for short periods of younger university scientists who have not yet achieved an international reputation. Concentrating first on the short visit by teachers of established reputation, an agreed Foreign University Interchange Scheme with Belgium came into operation in 1948. This was followed by similar arrangements with the Netherlands and Norway in 1949; with France and Austria in 1950; with Western Germany, Italy, Spain, Sweden and Switzerland in 1951; and with Finland and Portugal in 1952; arrangements were also concluded with Yugoslavia for an interchange scheme to commence in the academic session 1953-54. In all, the Scheme provides for a total of fifty-four visits to United Kingdom universities from thirteen countries each session, and for a like number of visits by British university teachers to universities in these countries.

Since the first Scheme came into operation in 1948, 252 such visits have taken place between universities in the United Kingdom and in the other participating countries. While the principles of procedure vary

* University Interchange Between the United Kingdom and Other European Countries, 1948-1953. (A Report on Reciprocal Schemes which are in Operation Between the United Kingdom and Other Countries in Europe, for the Promotion of Interchange Visits by University Teachers, and for the Award of Scholarships.) Pp. 24. (London: The British Council, 1953.)

† See *Nature*, 145, 306 (1940).

‡ See *Nature*, 156, 601 (1953).

slightly from one country to another, it has been proved that academic interchange can be organized centrally without undue threats to university autonomy and with economy in the administrative organization necessary. It is also clear that the short-period interchange visit meets a real need: no fewer than two hundred nominations are now received each year from United Kingdom universities for the incoming visits, and the number of invitations extended to British scholars by foreign universities leaves no doubt that the value of such visits is recognized just as fully by the other participating countries. Although some universities have independent schemes of their own which contribute to the total of interchange visits, it can be said that the Foreign University Interchange Scheme plays a substantial part in the renewal and furthering of academic contacts, with all that such contacts imply for international understanding and the advancement of knowledge.

Limited experiments have also been made in the provision of longer teaching visits. There are now four travelling lecturers attached to the French Institute in London who give regular courses at universities in the United Kingdom, and the British Council has to some extent met requests from abroad for similar teaching visits by British lecturers. Eight teaching visits for a month or more have been paid by British university teachers to universities in Austria, Finland and France. While the value of the longer teaching visit has been amply demonstrated, the reduction of the British Council's grant-in-aid has necessitated the termination of such visits for the time being.

On a different level, the interchange of students for postgraduate study has also become well established as a two-way traffic. For a number of years the British Council has offered scholarships tenable in the United Kingdom to students from other countries throughout the world. During the five academic sessions under review, 410 awards have been made, mostly for postgraduate study at a university for one year, to students from European countries with which reciprocal scholarship schemes are in operation. In reciprocation, foreign governments and universities are now offering annually for postgraduate study in fifteen European countries more than a hundred such awards to British students, mostly for one year; and the British Council has been asked by these governments and universities to assist in the administration of the scholarships, and usually to arrange with the Universities Advisory Committee for convening selection boards to recommend suitable candidates. The large number of applications received indicates that the facilities are fully appreciated on both sides.

There are also certain direct exchange arrangements between universities in the United Kingdom and in other European countries, and scholarships and fellowships offered by individual universities add to the total volume of student interchange. While the immediate results of interchange at this level may be less apparent than with interchange at the teaching level, the first-hand experience gained provides a valuable cultural link between the United Kingdom and other countries. On the evidence of this report alone, reductions in the British Council's grant-in-aid, which compel the interruption of such interchange at all levels, are scarcely sound economy.

There is a further reason why the Government should take care to ensure that the British Council

has sufficient financial resources to further interchange schemes on a reasonable scale. In December 1953, the Committee of Ministers of the Council of Europe signed in Paris five conventions, the most important of which will materially help young people from any of the sixteen member States in seeking admission to the universities of any of the others. The Convention commits the governments to the acceptance of international standards, but gives no guarantee of admission to a university, although the foreign student may be spared some troublesome examination when making application for admission.

The treaty powers are required to report progress in a year's time. No British Government either could or would attempt to dictate to the universities regarding the conditions or qualifications which the universities accept for admission, though British universities have been very unwilling to promise acceptance of equivalent qualifications of studies from outside the Commonwealth and the United States. Exceptions are in practice frequently granted, but both foreign students and officials are often perplexed by the apparent anarchy of regulations and variations from one university to another through which the wandering scholar has seldom shown much skill in finding his way. While the Government may well, particularly in view of the discussions at the Universities' Congress in July, expect the universities to give proof that they can really unite to make things easier for the individual student or scholar—who after all is nearer the wandering scholar or student of the Middle Ages than those whose movements are formally organized in interchange schemes—the Government must at least set the example of seeing that no short-sighted parsimony curtails what is already being done so admirably by the British Council and other bodies.

THE NATURE CONSERVANCY

AN article surveying the first two reports of the Nature Conservancy*, covering the work of the Conservancy for the period up to September 30, 1952, and for the year ended September 30, 1953, appears on p. 516 of this issue of *Nature*. Apart from their special scientific interest, they are of general interest as contributing to that wide understanding of the nature and importance of the work of the Conservancy which the Huxley Committee recognized as essential to the success of any system of nature reserves. Although the Nature Conservancy was constituted by Royal Charter "to provide scientific advice on the conservation and control of the natural flora and fauna of Great Britain; to establish, maintain and manage nature reserves in Great Britain, including the maintenance of physical features of scientific interest; and to organize and develop the scientific services related thereto", the management (and still more the designation) of nature reserves demands a large amount of local co-operation and support. Even on the scientific side, the Conservancy recognizes that the full achievement of some of its essential tasks, such as a continuing thorough biological survey of the British Isles, requires a good deal of co-operation

* The Nature Conservancy. Report of the Nature Conservancy for the period up to 30th September 1952. Pp. iii+83. 1s. 3d. net. Report of the Nature Conservancy for the year ended 30th September, 1953. Pp. iii+31. 1s. 3d. net. (London: H.M. Stationery Office, 1953.)

from individual naturalists and various specialized societies, and it is the Conservancy's duty to encourage and, where possible, extend this voluntary effort.

In the establishment of reserves in Great Britain, the Conservancy has obviously encountered some of the same difficulties as the National Parks Commission, and in its present judgment a considerable acceleration of the acquisition and declaration of new national nature reserves is essential in order to prevent the loss of sites of irreparable importance. This has proved a far more complex and difficult undertaking than was at one time supposed. Increasing pressure and mobility of population, and changing economic, technical and defence requirements are simultaneously reducing the available choice of surviving semi-natural habitats and are greatly increasing the difficulty of safeguarding them against competing claims, disturbance or deterioration. At September 30, 1952, nine nature reserves had been declared—two in Scotland and seven in England: a year later the total was only eleven, some of which represented parts only of the proposed eventual reserve areas, though the Kingley Vale and Ham Street reserves were substantially increased during the year. Negotiations over a number of other reserves had, however, led to agreement, although for some reason or other formal declaration during the year was not possible, and a much larger total of declarations during the coming year is anticipated. Special reference is made to Roudsea Wood, Westmorland, which, under a nature reserve agreement, will be used as a study and experimental area for the neighbouring Merlewood Research Station and to the Cairngorms. Approaches from the Scottish Committee of the Conservancy to landowners concerned regarding the establishment of a national nature reserve in the Cairngorms without prejudice to the climbing public and to the ultimate formation of a national park, in accordance with a resolution passed at a meeting in Inverness in January 1953, met with sympathetic response. By the end of September there was reasonable ground for hoping that any remaining points of difference might be cleared away and this group of mountains permanently safeguarded as a nature reserve.

The National Parks Act also empowers local authorities, in consultation with the Conservancy, to set up reserves, and although there are difficulties, particularly financial and in the provision of skilled biological management, the progress made indicates the existence of an encouraging amount of local understanding and support for the Conservancy's work. The first local authority to establish a nature reserve in its area was the Lincoln (Parts of Lindsey) County Council, which on August 1, 1952, made the requisite declaration of an area of some 300 acres of sand dune and salt marsh facing the Wash at Gibraltar Point. The East Lothian County Council has proceeded similarly with the declaration of Aberlady Bay, while in June 1953 a declaration by the Skegness Urban District Council in respect of that part of the Gibraltar Point range of dunes within its ownership and its boundaries brought the original area to 500 acres, all to be managed by the Lincolnshire Naturalists' Trust, Ltd. The Conservancy has also been consulted by the Cumberland County Council about the sand-dunes opposite Ravenglass, where there is an important gullery and ternery. Not only was great local interest shown in the complex relation between the bird colonies and the neighbouring human communities, but also all parties were agreed on the

importance of preserving the bird colony as an inheritance to be handed down to future generations.

During the past year, the National Trust has arranged for the Nature Conservancy to manage five properties of natural history interest. These are Llyn Idwal, on the Penrhyn estate; Blenheim Bog and North Fen, Esthwaite, in the Lake District; Soolt Head Island; and the Ruskin Reserve near Abingdon. There will be public access. The Conservancy has made temporary grants to the Royal Society for the Protection of Birds Reserve at Dungeness and to the Norfolk Naturalists' Trust Reserve at Hickling Broad for the employment of watchers or maintenance staff with the view of bringing back these reserves into first-class condition. While the most satisfactory division of responsibility and of labour between the various interested bodies has still to be worked out, the Conservancy has been much encouraged by the constructive and co-operative attitude which is so evident.

One reason for welcoming these reports and for giving them wide publicity is that they should help to remove the misunderstandings as to public access which have impeded negotiations, though probably to a lesser extent than in those leading to designation of national parks. Neither the designation of a park nor the declaration of a reserve confers any rights of public access, and the Act excludes declared nature reserves from its provisions for making access agreements in respect of what is defined in the Act as 'open country'. This does not mean that access to reserves will be generally denied. The Conservancy's policy is to allow as much access as is compatible with the proper scientific management of particular reserves. In those being used for experimental work, access must be carefully controlled; in some places access by permit, subject to compliance with stated conditions and to reasonable limitations of numbers, will be available to those generally interested. In other reserves the Conservancy hopes that the public will, by their behaviour, enable a policy of unrestricted access to be maintained.

A clear statement of the Conservancy's policy and the reasons governing the issue of permits to visit nature reserves which cannot be generally open to public access is appended to the report for the year ended September 30, 1953, and its wide circulation should both remove misunderstandings and encourage the local and general co-operation so helpful to the success of the Conservancy's work. Moreover, there is much material in these reports which demonstrates the importance of the scientific work of the Conservancy to the national economy. Now that its research stations at Merlewood, Morecambe Bay and at Furzebrook, Poole Harbour and its field stations (Ananoeum on Loch Maree and Moor House, Westmorland) are equipped and at work, and the initial reconnaissance and listing of sites of scientific importance is virtually finished in England (although much remains to be done in Scotland and Wales), it is to be hoped that the Conservancy will not be too pre-occupied with its research programme to neglect this important task of education and interpretation. Exposition at the appropriate moment of the significance of the results obtained in some of its scientific work, such as that on coastal erosion or the effects of spraying hedgerows and road-side verges with herbicides, or its studies on the ecology of the rabbit or of the introduction of reindeer in Scotland, could foster public understanding and goodwill, and thus help to ensure both that the modest sums required by

the Conservancy are provided by Parliament and that public access to the reserves causes neither abuse nor friction. It is satisfactory to note that in the latest report due stress is laid upon the development of the educational, information and intelligence aspects of the Conservancy's work and the preparation of suitable publications.

SICKNESS IN ENGLAND AND WALES

A RECENTLY published report from the Registrar General* describes three attempts to obtain statistics of morbidity, as distinct from mortality, in England and Wales. The study of mortality statistics was one of the main instruments of preventive medicine during the past hundred years. The statistics are extensive, detailed and complete. In their present form they represent the result of attempts to obtain information about human populations and not merely a by-product of administrative activity. By contrast, most existing statistics of morbidity are fragmentary and unsatisfactory, though they are of even greater potential interest than the mortality statistics. Most of the existing morbidity statistics, such as those derived from the records of Friendly Societies or hospitals, are incomplete in their coverage of the population; and most of them illustrate the limited value, for studies of general problems, of statistics originally collected for highly specialized purposes.

The three studies in the report under notice illustrate these general points, the first study being an account of the Survey of Sickness for the years 1948 and 1949. This Survey, using a designed sample, attempted to obtain information about sickness, duration of incapacity and frequency of medical consultation among the whole population. In principle, its results (here tabulated by age, sex and income of the persons interviewed) are of great importance in connexion with the operation of the National Health Service. In practice, the information obtained lacks precision, particularly as to the nature of the diseases causing incapacity. At best, the Survey provided information about what people thought was the matter with them. There is internal evidence, also, of the operation of memory effects. Nevertheless, the results of the Survey are interesting in themselves and will be even more interesting when they can be correlated with relevant statistics from other sources. Among these may be mentioned the results of an inquiry into hospital in-patient records conducted by the Registrar General, and the results of an analysis of claims to sickness benefit under the National Insurance Acts conducted by the Ministry of National Insurance. These results are apparently to be published in due course. In the meantime, it seems unfortunate that the Sickness Survey was abandoned in the interests of financial economy in 1952. Whatever the faults of this particular Survey may have been, investigations on similar lines offer the only means of obtaining morbidity statistics covering the whole population.

The second of the three studies illustrates another source of morbidity statistics, namely, records of admissions to hospital. The study is devoted to

statistics of mental disorders derived from the records of mental hospitals under the National Health Service. The results are interesting in themselves, but also serve to show the limitations of this source of information. The form designed for this inquiry proved too complicated to be satisfactorily completed by the hospitals. This is the converse of the usual situation in which the hospital administration produces records insufficiently detailed and standardized for the purposes of social medicine. The third study describes some of the results of the Cancer Registration Scheme relating to 1947 and 1948. Statistics for 1945 and 1946 have already been published elsewhere. This is an interim study describing an early phase of the construction of a complete statistical picture of this group of diseases. At present it covers only part of the population (that served by the hospitals taking part in the Scheme), but it achieves a high degree of diagnostic accuracy. It will in the end, no doubt, combine both accuracy and completeness. At present the tables give information about numbers of cases by age and sex and about the delay between first symptoms and starting of treatment for cancer of various sites.

EARTHQUAKES DURING 1953

THE five earthquakes which did most damage during 1953 occurred on February 12 (magnitude 7) in Persia; on March 18 (magnitude $7\frac{1}{2}$) in Turkey; during August a swarm (greatest on August 12, of magnitude $7\frac{1}{2}$) near Cephalonia; on September 10 (magnitude 6 $\frac{1}{2}$) near Cyprus; and on December 12 (magnitude $7\frac{1}{2}$) in Peru. In addition, nineteen other earthquakes were of magnitude 7 or more, the greatest being on November 25 (magnitude 8 $\frac{1}{2}$) near Japan.

Fourteen earthquakes had foci at depths of 200 km. or greater, the deepest occurring on April 14 (magnitude 7) in western Brazil and on November 4 off Korea, both having a depth of focus of 650 km.

The Persian earthquake in February occurred in the Province of Khorasan and devastated Shahrood, Torroud and neighbouring villages, killing hundreds of the inhabitants when their houses collapsed on them.

The Turkish earthquake of March 18 occurred south-east of the Dardanelles in the region of Chanak, Balıkesir, Yenice and Gonen, where more than a quarter of a million pounds sterling damage was done and hundreds of people were killed by falling debris and the fires which followed the earthquake.

The swarm of earthquakes in the Greek Ionian islands of Cephalonia, Ithaca and Zante culminated in the shock of magnitude $7\frac{1}{2}$ on August 12 and caused great damage, there being 394 deaths and a further 941 casualties (see *Nature*, August 22, p. 332). Argostoli, Lixouri and Zakynthos were particularly affected, and just after the earthquakes more than seventy-five thousand people were homeless. The International Seismological Association at Strasbourg reports that some 338 individual shocks occurred in the swarm of August 9-31.

The earthquake which did damage in the Paphos district of Cyprus on September 10 had a smaller magnitude than the others mentioned; but in the town of Ktima and the surrounding villages, including Stroumbi, Kithasi and Ayios Nikolaos, and even as

* The Registrar General's Statistical Review of England and Wales for the year 1949: Supplement on General Morbidity, Cancer and Mental Health. Pp. ix+186. (London: H.M.S.O., 1953.) 7s. 6d. net.

far as Limassol, much damage was caused; forty people were killed, a hundred injured, and just after the earthquake some four thousand were homeless.

From the reports from sixty-one observatories throughout the world, the epicentre of the earthquake of December 12 has been calculated by E. Peterschmitt and L. Behe at Strasbourg to be at lat. 3.7° S., long. 80.7° W., which is near the coast of Peru. Several people were killed as a result of this earthquake, and there was heavy property damage at Tumbes, Corrales and in the surrounding district.

Reports were received during the year directly from individual stations at Aberdeen, Arkansas, Belgrade, Cleveland (Ohio), Durham, Fayetteville, Karlsruhe, Kew, Lisbon, Lwiro (Belgian Congo), Pasadena, Perth (Western Australia), Toledo and Uccle; from collecting stations at De Bilt, Stuttgart, Wellington (New Zealand) and Zurich; and also from the International Seismological Association at Strasbourg and the United States Coast and Geodetic Survey in co-operation with Science Service and the Jesuit Seismological Association, where observations are collected and preliminary epicentres determined.

ERNST TILLOTSON

RADIO EVIDENCE OF THE EJECTION OF VERY FAST PARTICLES FROM THE SUN

By J. P. WILD, J. A. ROBERTS and
J. D. MURRAY

Division of Radiophysics, Commonwealth Scientific and
Industrial Research Organization, Australia

THE method of studying movements in the solar atmosphere by observing the spectrum of high-intensity radio noise from the sun has been discussed

in previous communications^{1,2}. It depends on the simple hypothesis that when the spectrum shows an abrupt low-frequency cut-off, the frequency of this cut-off can be identified with the critical escape-frequency at the source, and hence used for determining the height of the source in the solar atmosphere. The hypothesis has previously been applied to the outbursts of long duration for which the characteristic slow drift of the cut-off frequency can be explained in terms of disturbances which move outwards through the solar atmosphere at velocities¹ of the order of 500 km./sec. This result was confirmed in general terms by the directional observations of Payne-Scott and Little³. More recently, the critical-frequency hypothesis has been further substantiated by evidence that the observed cut-off must be attributed not to the natural profile of the emitted spectrum, but rather to severe attenuation of the lower frequencies in their escape from the sun⁴. This evidence was obtained by comparing profiles of the fundamental and the second harmonic (which is presumably unattenuated).

In the present communication we offer similar evidence for the application of the same hypothesis to another, more common, type of burst in which the frequency drift is much faster. Thence we infer the existence in the solar atmosphere of corpuscular ejections which move outwards at about one-fifth the velocity of light.

Type III Bursts

Using the previous nomenclature⁴, we shall refer to the two spectral classes mentioned above as type II (slow drift, duration 5–10 min.) and type III (fast drift, duration 5–10 sec.) respectively. In the course of observations between August 1952 and August 1953 with a wide-band (40–240 Mc/s.) spectroscopie, it was found that nearly all bursts, excluding those in noise storms, belonged to one of these two classes. In all, four outbursts of type II were recorded and several hundred bursts of type III. The latter

Fig. 1. Dynamic spectra of type III bursts. The shaded areas represent regions of high intensity in the frequency-time plane. (a) April 2, 1953, 0447 U.T. (b) Harmonic pair, Jan. 14, 1953, 0607 U.T. (c) Harmonic pair, June 6, 1953, 0136 U.T.

Fig. 2. Plot of derived motions in the solar atmosphere for a selection of type III bursts. The numbers on the curves give the approximate initial velocity in units of 10^4 km./sec. The first, third and fifth correspond to Figs. 1 a, c and d, respectively.

occurred sometimes in isolation but more commonly in small groups. On a few occasions we observed an intense compact cluster of type III bursts producing high-level radiation almost continuously for a period of 1-2 min. We have evidence that such clusters sometimes occur at the time of solar flares.

The dynamic spectrum of a simple type III burst, of the kind described previously¹, is shown in Fig. 1 a. The spectrum extends over the entire range, the rate of frequency-drift decreasing steadily with time. But the greater frequency-range of the present apparatus has revealed new features in type III spectra. First, the rate of drift is often observed to decrease so rapidly at the lower frequencies that the emitted peak becomes almost 'stopped' at a fixed frequency (see Fig. 1 b). Secondly, it is common to find bursts occurring in harmonic pairs, in which spectral features of a burst are duplicated at double the frequency (see Figs. 1 b and c). Just as in the case of type II bursts, comparison of the profiles of fundamental and second harmonic normally indicates that the low-frequency skirt of the fundamental has been cut off during escape. It is this result that justifies the application of the critical-frequency hypothesis to type III bursts.

Two explanations based on this hypothesis have been suggested to account for the systematic frequency-drift of type III bursts². In one, the drift is attributed to the motion of a disturbance which travels out-

ward through the solar atmosphere, thus passing through regions of steadily diminishing electron density. In the other, it is attributed to the rapid dispersion of a stationary, dense cloud situated in the outer corona. The latter interpretation now seems untenable because, with any reasonable distribution of electron-density in the cloud, the predicted band-width would be much broader than that observed in many of the bursts (for example, Fig. 1 c). In what follows we adopt the former interpretation and show that it accounts naturally for the known properties of the bursts. On current evidence the case in favour of this interpretation seems strong in view of the very reasonable physical picture which it yields and the simplicity with which it explains the more complicated disturbances ('compound bursts') discussed below.

The derived movements associated with a representative selection of type III bursts are shown in Fig. 2 as a plot of coronal height against time. In this diagram the critical-frequency levels have been calculated from the Allen-Baumbach model and the observed range of levels has been extended by using second harmonics. The initial velocities lie in the range 3×10^4 – 10^5 km./sec. (0.1 c.–0.3 c.). Although in some cases the velocity remains almost constant throughout the observed range of heights, none has yet been found with outward acceleration. However, deceleration is common, and in cases such as Fig. 1 b (corresponding to the last curve of Fig. 2), the disturbance is apparently brought to rest at some height within the observed range. In some bursts there is evidence of considerable spread in velocity, whereas in others the narrow band-width means that the spread could be no greater than about 20 per cent of the mean velocity.

The moving disturbances may be explained as corpuscular streams, since at such high velocities protons and electrons would pass through the corona almost unimpeded by collisions. We may note that the emission of very fast particles at the time of solar flares is consistent with a known terrestrial phenomenon. At a velocity of 5×10^4 km./sec., particles reaching the earth would do so 50 min. after the onset of the flare. This is typical of delays observed between solar flares and the increases in cosmic-ray intensity that occasionally accompany

Fig. 3. Plot of the derived motions in the solar atmosphere for a compound burst (Sept. 1, 1953, 0836 U.T.).

them⁶. It is possible, therefore, that type III bursts are caused by cosmic rays of solar origin. However, it should be remarked that unless the particles are much heavier than protons, their energies at velocities of the order of 5×10^4 km./sec. must be considerably lower than those deduced by cosmic-ray investigators. Nevertheless, the 'low' velocities seem to offer the only simple explanation of the long time delays.

Compound Bursts

We now know that two kinds of activity may occur at the time of solar flares: the type II outbursts and the type III clusters. During the year, we have recorded four of the former and ten of the latter. Either kind may occur without the other, but on three occasions we have observed the combination of the two. On each occasion the type II burst followed the type III cluster after a time delay of several minutes.

An example is shown in Fig. 3, plotted in terms of heights in the solar atmosphere. The calculated velocities are 230 km./sec. for the type II burst and 1.0×10^5 km./sec. for the type III. Both the velocity and the time delay of the type II differ considerably for the three cases observed. Yet in each case extension of the velocity lines towards the origin yields a point of intersection in the lower corona within 10^4 km. of the photosphere. This suggests that the two portions of the compound burst are associated with disturbances, perhaps streams of matter, ejected simultaneously from a common source located low in the solar atmosphere. Such an 'explosion' may well be the primary cause of the flare.

Speculation on the physical nature of this phenomenon has led us to consider several possible mechanisms.

(1) An explosion involving thermo-nuclear or chain reactions between nuclei of light elements, the products being emitted with characteristic velocities. Such explosions do not seem feasible at the low densities believed to exist in the solar atmosphere, but it is not known whether they may occur slightly below the photosphere.

(2) A sudden accelerating process involving large-scale electric and magnetic fields. The two velocities could result from the acceleration of charged particles of very different mass in the same field. However, the large velocity ratio may be difficult to explain.

(3) A disturbance of some kind which gives rise to the combination of a fast corpuscular ejection and a shock wave. It is noteworthy that the typical slow (type II) velocity is of the order of the mean speed of thermal protons in the corona, which may be identified with the velocity of sound.

We wish to thank Mr. W. C. Rowe and Mr. J. Joise for assistance in the observational phase of this work, and also Prof. E. E. Salpeter for a valuable discussion on nuclear reactions in the sun.

SOME PHYSICAL PROPERTIES OF METALLIC PLUTONIUM

FOLLOWING a recent declassification decision, it is now permissible to disclose some of the properties of metallic plutonium (Pu, $Z = 94$).

Between room temperature and its melting point, pure plutonium was found to exist in five allotropic modifications, labelled α , β , γ , δ , ϵ . The temperatures at which the phase changes occur are given in Table 1, determined by dilatometry at heating- and cooling-rates of about $1\frac{1}{2}$ deg. C. per min.

Table 1. TRANSITION TEMPERATURES ($^{\circ}\text{C}$.)

	Heating	Cooling
$\alpha \rightarrow \beta$	126	85
$\beta \rightarrow \gamma$	235	About 160
$\gamma \rightarrow \delta$	280	250
$\delta \rightarrow \epsilon$	480	480

During cooling, the $\epsilon \rightarrow \delta$ change occurs with little or no temperature hysteresis; but the remaining transformations show considerable sluggishness, which makes it difficult to quote temperatures for the start of the $\delta \rightarrow \gamma$ and $\gamma \rightarrow \beta$ changes. The $\beta \rightarrow \alpha$ transformation commences sharply at 85°C ., and continues slowly at room temperature.

The density of α -plutonium at room temperature has been determined by the measurement and weighing of pressed geometrical shapes, and by displacement. The approximate densities of the other phases have been found from dilatometer measurements. Typical figures are given in Table 2: the values for the β , γ , δ and ϵ phases refer to the low-temperature end of the stable range of the phase.

Table 2. DENSITIES OF PHASES OF PLUTONIUM (gm./c.c.)

α	β	γ	δ	ϵ
19.0	17.4	16.0	15.4	16.4

Features of interest in this table are the considerable increase in density on passing from the δ - to the ϵ -phase, and the large difference in density between the densest (α) and the least dense (δ) phase.

Table 3 gives values for the coefficients of thermal expansion of the various phases. In the α -, β - and δ -phases the coefficients vary considerably with the temperature, but in the γ - and ϵ -phases the expansions are almost linear. The values given are taken at the middle of the appropriate temperature-range.

Table 3. COEFFICIENTS OF LINEAR THERMAL EXPANSION (parts in $10^6/^{\circ}\text{C}$.)

α	β	γ	δ	ϵ
(below 70°C .)	(above 70°C .)	(below 190°C .)	(above 190°C .)	
40	66	32	54	48 -33 20

A most interesting feature is the negative temperature coefficient of expansion shown by δ -plutonium. This behaviour is perhaps unique in a polycrystalline pure metal. At the low-temperature end of the stability range of the δ -phase, the coefficient of expansion is very small and becomes negative at high temperatures, getting numerically greater as the temperature increases to the $\delta \rightarrow \epsilon$ change point at 480°C .

The work described above was directed by Mr. G. L. Hopkin, to whom I am indebted for encouragement and advice. I also acknowledge help from

numerous colleagues, particularly Messrs. R. G. Hambling, A. Knight and R. Willows of this Establishment. My thanks are due to Sir William Penney, director of this Establishment, for permission to publish this communication, and to Sir John Cockcroft, director of the Atomic Energy Research Establishment, for facilities.

W. B. H. LORD

Atomic Weapons Research Establishment,
Aldermaston, Berkshire.
Feb. 5.

CONCURRENTLY with the above work, a more extensive programme of research was carried out at the Atomic Energy Research Establishment, Harwell. The transition temperatures between the five allotropic modifications of plutonium have been determined by several methods, the results being summarized in Table 4. The temperatures quoted are approximate typical values, given to the nearest multiple of five degrees; extensive experiments show considerable variations from specimen to specimen. In most cases actual experimental values are within a range of $\pm 5^\circ \text{C}$; but isolated results have been obtained well outside this range.

The electrical resistance and the coefficients of electrical resistance and thermal expansion on heating are given in Table 5. Behaviour on cooling is complicated by severe hysteresis effects and sluggish transformations, so that to quote simple values without extensive qualification would be misleading. Values for cooling are therefore omitted.

The density of α -plutonium has been determined by the displacement method, and values for the other phases have been calculated from the dilatation curves on heating. Variations in the density have been observed from specimen to specimen. The value quoted is for a specimen after standing for several months at room temperature. A typical value for specimens immediately after dilatation runs is about 18.7 gm./c.c., the low figure being presumably due to the retention of other phases. The values given for the β -, γ -, δ -, ϵ -phases are typical for these phases at the lower end of their stable range (Table 6).

Table 6

Phase	Density (gm./c.c.)
α	19.25
β	17.3
γ	16.7
δ	15.7
ϵ	16.8

Full discussion of the theoretical implications will become possible only when security limitations permit the disclosure of some other properties of plutonium; but in addition to the negative coefficient of thermal expansion of the δ -phase, and the large density difference between the latter and the α -phase, the following points may be noted:

(a) The relatively high values of electrical resistivity and the negative and extremely low temperature coefficients of resistance of some of the phases.

(b) The large hysteresis associated with the $\delta \rightarrow \gamma$, $\gamma \rightarrow \beta$ and $\beta \rightarrow \alpha$ phase-changes, and the complete absence of hysteresis in the onset of the δ -phase change which, however, proceeds only partly to completion, even with long soaking periods.

(c) The large variations in properties between one specimen and another, which it is difficult to account

Table 4

Phase	Transition temperatures ($^\circ\text{C}$)					
	Thermal analysis*		Dilatometry†		Electrical resistance*	
	Heating	Cooling	Heating	Cooling	Heating	Cooling
$\alpha \rightleftharpoons \beta$	140	90	125	80‡	125	90‡
$\beta \rightleftharpoons \gamma$	235	145‡	235	Transformation obscured on all specimens due to sluggishness	230	160‡
$\gamma \rightleftharpoons \delta$	325	345‡	315		325	325‡
$\delta \rightleftharpoons \epsilon$	475	475	490		490	490‡
Melting and freezing points	640	640		480‡		

* Rates of heating and cooling, approximately 2 deg. C. per min.

† Rates of heating and cooling, approximately 1 deg. C. per min.

‡ Ill-defined transitions on some specimens; arrests obscured on others.

§ Start of transition; transformation occurs progressively to room temperatures, and sometimes continues isothermally.

|| On cooling, the change does not appear to go to completion; the density decreases only from 16.3 to about 16.1.

Table 5

Phase	Resistivity* (microhm cm.)	Coefficient of electrical resistance on heating per deg. C. ($\times 10^{-4}$)	Linear coefficient of thermal expansion on heating per deg. C. ($\times 10^{-5}$)
α	150	-20 to -40‡	+50 to 65‡
β	116	-10	+43
γ	115	-4 to -20‡	+39
δ	111	+7	+27‡
ϵ	123	—	+20‡

* Mean figures for several specimens; they refer to the low-temperature end of each range. The variation from specimen to specimen is about ± 3 microhm cm. The values for β -, γ -, δ - and ϵ - have been corrected for volume changes on the basis of isotropic expansions from the α -phase.

† The curve is not linear; these are limiting values for several specimens.

‡ These are limits for several specimens; one specimen gave a value of $+20 \times 10^{-5}$.

§ The curve is not linear over the whole range; this is a typical value for the linear portion of the curve.

|| Typical values for several specimens; variations from approximately 5 to 30×10^{-5} have been observed on some specimens.

for by the presence of impurities if normal experience is taken as a basis for comparison.

Many features of the behaviour of plutonium have been necessarily omitted from this short summary; but it is hoped to publish a more detailed account of the experimental results elsewhere.

We wish to thank Dr. H. M. Finnieston and Dr. M. B. Waldron for helpful criticism and discussion during the work, and Sir John Cockcroft, director of the Atomic Energy Research Establishment, for permission to publish this communication.

Absolute Configuration of Cholesterol

In the course of more extensive work on degradation of cholesterol, we have made a stereochemical correlation which seems to justify an interim report.

Ozonolysis of cholest-14-en-3 β -ol (I) and pyrolysis¹ of the product at 210–220° in cyclohexane gave, as one fragment, an $\alpha\beta$ -unsaturated aldehyde (II) which formed a crystalline, levorotatory semicarbazone (III) from (+)-citronellal by the following process:

The semicarbazone from cholesterol had a melting point of 133° (somewhat variable owing to polymorphism), $[\alpha]_D^{25} - 24.5^\circ$ ($c = 1$, dioxan). The semi-

carbazone from citronellal had a melting point of 133°–135°, $[\alpha]_D^{25} - 22^\circ$ ($c = 1$, dioxan). There was no depression of melting point on admixture. The infra-red spectra (in potassium bromide) were identical. X-ray diffraction photographs of single crystals confirmed the essential identity of the two specimens, though there was a difference in gross crystalline habit, possibly due to slight racemization of one specimen. We are obliged to Mrs. O. Kennard for this comparison and to Dr. R. K. Callow for the infra-red spectra.

The aldehyde (II) contains C_{14} of cholesterol as the sole asymmetric centre, and the spatial relationship of C_{14} with the other asymmetric centres of cholesterol is known, mainly from the crystallographic analysis of cholesteryl iodide². Briefly, if the absolute configuration of the ring system in steroids is represented correctly by the conventional projection (as in (I), for example), then the absolute configuration about C_{14} is represented by (IV)³.

On the other hand, (+)-citronellal (V) has been degraded to (+)-methyl-succinic acid in the sense indicated by the dotted lines⁴. The latter acid, according to Fredga's evidence⁵ obtained from a study of 'quasi-racemates', belongs to the D-glycer-aldehyde stereochemical family and has the configuration (VI). If this assignment is accepted, it follows that the assignments (V) and (IV) are also true and that the conventional projection of the steroid molecule really represents the absolute configuration. This confirms the conclusions drawn by Mills⁶ from optical rotation differences and by Prelog⁷ from the stereochemical course of asymmetric syntheses.

A detailed account of this work will be published elsewhere.

Structure of Bacitracin A

In a recent letter, Porath¹ reported that bacitracin A with an activity of 60 units/mgm. could be obtained by chromatography on charcoal. From an analysis of the peptides formed by hydrolysing this material with 6 N hydrochloric acid for 72 hr. at 37°, he tentatively suggested a partial structure for the molecule.

We have studied the products of hydrolysis of a sample of commercial bacitracin (Commercial Solvents Cor-

poration, Lot 311, 47 international units/mgm.), and of a sample of bacitracin A hydrochloride (72 international units/mgm., corresponding to 77 units/mgm. for the free base) prepared by a short counter-current distribution in the system described by Newton and Abraham³. So far as our analysis has proceeded, the two samples have given similar results. The samples were hydrolysed with 11 N hydrochloric acid at 37° for periods varying from one to six days, and in some experiments the latent thiol group^{3,4} was oxidized to SO₂H with performic acid⁵. Electrophoresis and chromatography on paper were used to separate and characterize the resulting peptides, and 1:2:4-fluorodinitrobenzene⁶ to determine their N-terminal amino-acids. Although a number of these peptides conform to portions of the amino-acid sequence postulated by Porath¹, others appear to have structures which are inconsistent with this sequence as a whole.

After hydrolysis for six days, significant amounts of free histidine, ornithine, aspartic acid and glutamic acid were found. Among the dipeptides which appeared to be present were leucylglutamic acid, β -sulphoalanylleucine and isoleucylcysteine acid. Other products included a tripeptide of cysteine acid, leucine and glutamic acid (with cysteine acid as the N-terminal amino-acid) and a tetrapeptide of isoleucine, cysteine acid, leucine and glutamic acid (which appeared to have isoleucine as the N-terminal amino-acid). These results would require the following sequence to be present in bacitracin A:

Further results suggest that the left-hand side of this sequence can be extended through a peptide containing ornithine, phenylalanine and isoleucine residues (with ornithine as the N-terminal amino-acid), and that the glutamic acid on the right-hand side is close to aspartic acid. Since the molecule appears to contain a cyclic chain^{3,4}, this arrangement, like the structure suggested by Porath¹, implies that most of the polar side-chains are grouped together on one part of the ring and most of the non-polar side-chains on the other.

There is general agreement that the δ -amino group of the ornithine residue and the imidazole group of the histidine residue in bacitracin A react with 1:2:4-fluorodinitrobenzene, but that the ϵ -amino group of the lysine residue is masked^{1,3,4}. In addition to the basic groups provided by the ornithine and histidine residues, bacitracin A contains a third basic group, which titrates in the region of a peptide α -amino group³. Craig, Hausmann and Weisiger⁴ have stated that bacitracin A behaves as though it contains two free amino groups in the Van Slyke determination of amino-nitrogen. Newton and Abraham³ reported that, after reaction with 1:2:4-fluorodinitrobenzene, bacitracin A yielded dinitrophenyl-leucine or -isoleucine on hydrolysis; but Porath¹ was unable to repeat this observation, and Ingram⁷ could demonstrate no N-terminal amino-acid by reductive methylation. We have now confirmed that hydrolysis of our sample of dinitrophenyl-bacitracin A yields an ether-soluble dinitrophenyl-derivative which runs on paper chromatograms⁸ like dinitrophenyl-isoleucine and yields a substance which behaves like isoleucine on hydrolysis with baryta⁹. The dinitrophenyl-deriva-

tive of commercial bacitracin (which contains some bacitracin B) yields, in addition, a substance which behaves like dinitrophenyl-valine. However, the yield of dinitrophenyl-isoleucine (and dinitrophenyl-valine), while too large to be neglected, is considerably less than the yield expected from one N-terminal group per molecule. Moreover, an attempt to degrade bacitracin by the method of Edman¹⁰, using the procedure of Landmann, Drake and Dillaha¹¹ to characterize the products on paper chromatograms, yielded only about 5 per cent of the theoretical amount of 3-phenyl-2-thiohydantoin expected from an N-terminal isoleucine. It therefore remains uncertain, from these experiments, whether the third basic group of bacitracin A is responsible for the formation of dinitrophenyl-isoleucine, or whether this group is part of some hitherto uncharacterized structure in the molecule.

Evidence for the Existence of Two Types of Ribonucleic Acid

THE predominant internucleotide link in ribonucleic acids is now known to be a phosphodiester link between the 3' position of one nucleoside residue and the 5' position of the neighbouring residue, regardless of whether the nucleoside residue contains a purine or a pyrimidine¹. Assuming for the moment that all the nucleic acid chains have equivalent numbers of base and phosphate residues, the chains may be built up in one of two ways. These are represented diagrammatically in formulae I (a and b) and II, where O₁, O₂, and O₃ represent positions 2', 3' and 5' of the nucleoside residues, (P) a phosphate group; in each case the two terminal and one internal nucleoside residues are depicted.

A ribonucleic acid of type I may be considered as being built up of nucleoside 3' phosphates, whereas type II is built up of nucleoside 5' phosphates. For convenience, we shall call those end residues which bear only a phosphate group joining them to the remainder of the chain terminal 'nucleoside residues', and those which bear an additional phosphate group, terminal 'nucleoside 5'', or '3'', or 2':3' cyclic phosphate residues', depending upon the position occupied by the phosphate group.

In the ribonucleic acids from yeast and turnip yellow mosaic virus, Markham and Smith² showed the presence of two main types of end groups, namely, terminal purine or pyrimidine nucleoside 3'

(Ia)

(Ib)

(II)

(or 2') phosphates and purine nucleoside 2':3' cyclic phosphates. The other ends of the chains were assumed to be occupied by nucleoside residues; thus the nucleic acids were taken to be of types Ia and Ib.

We now have evidence that, in the case of the ribonucleic acids from tobacco mosaic virus and potato virus X, a substantial proportion of the chains are of type II. From Brown and Todd's theory of the acid and alkaline degradation of ribonucleic acid⁸, a chain of type I will yield only nucleoside 2' and 3' phosphates on alkaline hydrolysis, whereas that of type II will, in addition, give nucleosides from the terminal nucleoside residues, and a mixture of nucleoside 2':5' and nucleoside 3':5' diphosphates from the terminal nucleoside 5' phosphate residues. Tobacco mosaic virus nucleic acid was prepared by heating purified virus to 93°C. for 3 min. in neutral solution in the presence of salt. The denatured protein was centrifuged off and the nucleic acid precipitated by the addition of two volumes of ethanol. When an alkaline hydrolysate (*N* potassium hydroxide at 20° for 18 hr.) of tobacco mosaic virus nucleic acid is run on paper electrophoresis in borate buffer at pH 9, in addition to the single band of mononucleotides, two other ultra-violet absorbing bands are observed. One band moving faster than the mononucleotides has the expected mobility of the nucleoside diphosphates. The other migrates more slowly than the mononucleotides, in the position of the ribonucleoside borate complexes.

The nucleoside diphosphates migrate in the expected positions on paper electrophoresis at pH 7.4 and pH 9 (when they bear four negative charges due to the primary and secondary dissociations of the two phosphate groups) and on paper chromatography in isopropanol-water-ammonia⁹. On paper electrophoresis at pH 3.5 they separate into three bands corresponding to (a) an unresolved mixture of cytidine and adenosine diphosphates, (b) guanosine diphosphate and (c) uridine diphosphate. On hydrolysis in *N* hydrochloric acid for 1 hr. at 100° and paper chromatography in isopropanol-hydrochloric acid⁹, the purine nucleoside diphosphates yield adenine and guanine while the pyrimidine nucleoside diphosphates are unchanged and move in the positions of cytidylic and uridylic acids. By these means we have isolated

substances with the expected ultra-violet absorption spectra of the diphosphates of adenosine, guanosine and uridine, and which were found to have molar ratios of base to phosphorus of approximately 1:2.

The nucleoside band isolated by electrophoresis at pH 9 contains ribose but no phosphorus, and on paper chromatography in *n*-butanol-water-formic acid⁹ separates into bands moving in the positions of the nucleosides. Adenosine, which occurs in the greatest amount, has been identified by its ultra-violet absorption spectrum.

By hydrolysis with *N* hydrochloric acid and chromatography in isopropanol-hydrochloric acid the relative proportions of the four nucleosides and the four nucleoside diphosphates have been measured. These were very different from the proportions of the four nucleotides in the entire nucleic acid. The relative proportions of adenosine among the nucleosides and of uridine diphosphate among the nucleoside diphosphates are considerably higher than those of adenylic and uridylic acids respectively in the whole nucleic acid.

The intact nucleic acid was treated with purified prostate phosphomonoesterase at pH 5.3 for 18 hr. at 37°, precipitated with two volumes of ethanol and hydrolysed with alkali. Virtually no nucleoside diphosphates were then found, although the nucleosides had increased relatively in amount. This demonstrated that the diphosphates did in fact originate from terminal residues bearing singly esterified phosphate groups. From the increase in nucleosides, it appears that terminal nucleoside 2' or 3' phosphate groups were also present⁸.

In tobacco mosaic virus nucleic acid, about one residue in fifty yields a nucleoside diphosphate on alkaline hydrolysis, while the proportion of nucleoside end-groups is somewhat higher. This would suggest that the size of tobacco mosaic virus ribonucleic acid is of the same order as that of the turnip yellow mosaic virus¹⁰ and is considerably smaller than has been deduced from physical measurements¹¹. While alkaline hydrolysates of potato virus X ribonucleic acid contain similar amounts of nucleosides and nucleoside diphosphates, these substances were not detected in the ribonucleic acid of turnip yellow mosaic virus, thus confirming that the latter is of type I. They appear to be present in small amounts in ribonucleic acids from *Bacterium coli* and mouse liver.

It has been shown that the terminal nucleoside 5' phosphate residues did not originate during the preparation of the tobacco mosaic virus nucleic acid in the following ways: (1) intact tobacco mosaic virus hydrolysed with alkali gives nucleoside diphosphates; (2) heating turnip yellow mosaic virus nucleic acid, in the way used during the preparation of tobacco mosaic virus nucleic acid, does not lead to the appearance of nucleoside diphosphates in alkaline hydrolysates, and (3) the proportions of nucleosides and nucleoside diphosphates in alkaline hydrolysates of tobacco mosaic virus nucleic acid are not changed by varying the method of preparation of the nucleic acid, or by pretreatment of the virus by grinding or with ultrasonic radiation.

We conclude that, in tobacco mosaic virus and potato virus X ribonucleic acids, a large proportion of the chains are of type II. In addition, some of the chains are of type I, while the non-equivalence of nucleosides and diphosphates in alkaline hydrolysates shows that chains with other combinations of the four possible types of end groups must exist.

Examination of the distribution of these different types of end groups in nucleic acids from related strains of the viruses may show differences not apparent in the gross composition of the nucleic acids.

Detection of Free Hydroxyl Radicals during the Oxidation of Cellulose in Air

It is well known that when dyed cellulose fabrics are printed with pastes containing the reducing agent sodium sulphonylate formaldehyde, and steamed, in order to produce a white design on a coloured ground, the white parts of the pattern are sometimes weakened^{1,2}. The weakness is due to oxidation of the cellulose at the printed places, and it has been shown that the oxidation occurs only when the fabric is left in humid conditions for some hours after the steaming operation and before the residual printing paste is washed off. During this period the unused reducing agent undergoes oxidation by atmospheric oxygen, and this reaction is accompanied by one in which the cellulose is oxidized. The simultaneous oxidation of sodium sulphonylate formaldehyde and cellulose, in the absence of the printing adhesives, has recently been investigated in these laboratories. In some of these experiments cellulose fabric was impregnated with a solution of neutral sodium sulphonylate formaldehyde to which naphthalene-1-sodium sulphonate had been added. The impregnated fabric, after storage in a moist atmosphere for several hours, was made alkaline and treated with an excess of diazotized sulphanilic acid, whereupon a pink colour developed. This pink colour can only have arisen by the coupling of the diazonium compound with a naphthol derived from the naphthalene sulphonate, and it is difficult to conceive any way in which hydroxyl groups can have been introduced into the naphthalene sulphonate except as free hydroxyl radicals (cf. Weiss and Stein^{3,4}). No evidence, either of the oxidation of cellulose or of the presence of free radicals, has been obtained when sodium bisulphite, sodium bisulphite formaldehyde, or alkaline sodium sulphonylate formaldehyde are oxidized on cellulose in this manner. Neutral sodium sulphonylate formaldehyde is also oxidized quite readily on glass fabric, but without formation of hydroxyl radicals.

It appears, therefore, that free radicals are involved in the oxidation of cellulose under the conditions used in these experiments, and that the radicals can only be detected when both the sodium sulphonylate

formaldehyde and the cellulose are undergoing oxidation simultaneously.

Electrophoretic Separation on Filter Paper of the Soluble Liver-Cell Proteins of the Rat using Borate Buffer

THE electrophoretic analysis by the ordinary Tiselius apparatus of the soluble proteins isolated from rat liver has already been described¹⁻³; but the constituent components reported by these authors differed one from the other.

In order to find a convenient method with consistent results, an electrophoretic separation on filter paper of the soluble proteins of liver cells of the rat was attempted in a way similar to the well-known method for serum proteins. This communication deals with such a separation of the soluble proteins obtained by homogenization and differential centrifugation from livers of healthy rats.

Fig. 1. Electrophoretic separations on filter paper of the soluble liver cytoplasmic proteins of the rat. The strips were stained using naphthalene black. (a) Veronal buffer pH 8.6, μ 0.1. (b) Phosphate buffer pH 8.0, μ 0.1. (c) Borate buffer pH 8.6, μ 0.18. The five bands are numbered from 1 to 5 in order of mobility. (d) Material used 48 hr. after preparation (borate buffer).

The following technique has been used for overcoming some difficulties and stabilizing a reproducible method.

A combination of a freeze-drying process and homogenization in isotonic sucrose solution permits a concentration of proteins suitable for paper electrophoresis to be obtained without denaturation of the proteins. The livers removed from the exsanguinated animals were frozen within 15 min. after death and dried *in vacuo*. The gently powdered dried material was suspended in isotonic sucrose solution containing 0.2 per cent of versene, and homogenized with a Potter-Elvehjem glass homogenizer. The isolation of cellular fractions was then carried out by differential centrifugation⁴. The final supernatant containing the soluble cytoplasmic proteins was clear and transparent with pH 6.8 and a protein concentration, depending upon the initial dilution, of about 4 per cent.

Immediately after preparation, 0.02 ml. of this solution was allowed to run overnight on strips of Whatman No. 1 filter paper in an electrophoretic apparatus similar to that described for serum proteins⁵ (potential gradient 15 V. per cm.).

A series of experiments was carried out to find a suitable buffer solution which would differentiate the velocity of migration of the various protein fractions. The only suitable solution was found to be a borate buffer of pH 8.6 and $\mu = 0.18$.

A clear resolution of five major protein components was obtained and developed by staining the strips with naphthalene black (Fig. 1c). Figs. 1a and b show the less satisfactory separations with a veronal and a phosphate buffer of pH 8.6 and $\mu = 0.1$.

An important point on which the success of the separation depends is the freshness of the prepared material. The ageing of the protein solutions was investigated and it was found that a noticeable alteration occurs within twenty-four hours, and within forty-eight hours the proteins migrate as a single band with no separation (Fig. 1d).

I wish to thank Dr. D. J. R. Laurence for helpful advice.

A Crystalline Chlorophyll-Protein Complex from *Chlamydomonas*

THE isolation of a crystalline chlorophyll-protein complex from clover was recently reported and illustrated by Takashima¹. Spikes, Lumry and Anderson² repeated the crystallization of this complex from thirty species of plants. We have also obtained material with a very similar appearance from many green leaves; for example, clover, *Trifolium repens*; cocksfoot, *Dactylis glomerata*; bracken fronds, *Pteridium aquilinum*. In addition, an apparently crystalline chlorophyll-protein complex has been obtained from a species of alga, *Chlamydomonas*.

Chlamydomonas dorsoventralis (Culture Collection of Algae, Cambridge) was grown in an inorganic salt medium³ aerated with 5 per cent carbon dioxide - air under artificial illumination. The cells were harvested, suspended in a small volume of medium and an equal volume of α -picoline added. The suspension was then centrifuged and dioxan added to the clear green supernatant to a final concentration of 20 per cent. On leaving overnight at 0° C., microscopic green crystals of the chlorophyll-protein complex separated in rosettes. These were recrystallized from α -picoline and dioxan mixture. The material formed roughly equidimensional clusters, each appearing to have grown dendritically from a centre.

Chlorophyll was extracted from the complex by organic solvents, and the absorption spectrum of a solution of the pigment in ether indicated the presence of chlorophylls *a* and *b*. The usual amino-acids were detected by paper chromatography in a hydrolysate of the complex.

Similar crystals were also obtained from a species of marine *Chlamydomonas* kindly provided by Dr. C. P. Spender. In contrast, the above procedure failed to extract any coloured material from intact cells of *Chlorella vulgaris*, grown with either carbon dioxide or glucose as source of carbon.

We wish to thank Dr. L. Fowden for the culture of *Chlorella* and the Agricultural Research Council for financial support.

Separation and Estimation of Chitosamine and Chondrosamine in Complex Hydrolysates

THE estimation of hexosamines in hydrolysates of complex biological materials, containing both protein and carbohydrate parts, has for some years been recognized as one of the more important analytical problems of biochemistry. The separation and identification of the two hexosamines, chitosamine (glucosamine) and chondrosamine (galactosamine), known to occur in the animal organism, is likewise difficult. The use of ion-exchange resins offers a convenient technique for separating the hexosamines from each other and from other substances.

Moore and Stein¹ report the position of a hexosamine peak using elution chromatography with both 100-cm. and 15-cm. columns of 'Dowex 50' resin. Partridge and Elsdon² have separated chitosamine from chondrosamine on 100-cm. columns of 'Dowex 50'; the peaks emerge in the region 250-350 fractions from the beginning of the run where the citrate buffer of pH 4.25 is emerging. Unfortunately, the hexosamine peaks overlap some of the amino-acid peaks, necessitating the analysis of alternate fractions by the ninhydrin³ and the Elson and Morgan⁴ methods, respectively, to enable a distinction to be made. In addition, we have found the position of the peaks

Fig. 1. A portion of a chromatogram of a protein-carbohydrate complex hydrolysate on a 15-cm. column of 'Dowex 50', showing separation of the hexosamines

liable to vary somewhat according to an unknown factor, possibly the flow-rate. Gardell⁴ has separated glucosamine from galactosamine on 'Dowex 50' columns using 0.3 *N* hydrochloric acid as eluant, and Boas⁵ used the same resin to remove interfering substances from hexosamine solutions. Both authors utilized modified Elson and Morgan⁶ techniques to determine the hexosamines.

Recently, in connexion with the analysis of a protein-carbohydrate complex isolated from compact bone, we have succeeded in separating chitosamine and chondrosamine quantitatively on 15 cm. $\times$ 0.9 cm. columns of 'Dowex 50' using the standard procedure of Moore and Stein¹. The positions of the peaks are shown in the accompanying figure, where the optical density of the solution, compared with water, is plotted against the fraction number. The chitosamine peak at fraction 40 is well separated from the chondrosamine peak at fraction 50. The hexosamine peaks are also separated from tyrosine and phenylalanine, from the amino-acids emerging before these and from the small peak at fraction 25, which is an artefact arising from the change of buffer at fraction 23 (0.1 *M* sodium citrate, pH 4.95 to 0.1 *M* sodium phosphate, pH 6.75). Histidine and hydroxylysine (not shown in the figure) emerge after the hexosamines and without overlap. The only known amino-acid emerging with the hexosamines is tryptophan, which is unlikely to cause difficulty in hydrolysates, since it is completely destroyed on heating with acid.

The complete separation of the hexosamines from amino-acids on the 15-cm. column enables the reliable ninhydrin procedure² to be used for estimation in place of the less accurate method of Elson and Morgan⁶. Convenience is also gained, compared with the use of the 100-cm. column, since a smaller number of fractions is required for the emergence of the amino-sugars. Both chitosamine and chondrosamine give the same colour intensities with ninhydrin as an equimolecular weight of leucine, that is, colour yield is 1.00%. Both hexosamines were recovered quantitatively from the column, when added as the pure hydrochlorides. The method, therefore, provides an accurate means of determining small quantities of chitosamine and chondrosamine in hydrolysates of complex polysaccharides, whether or not proteins are also present. The decomposition of hexosamines, in the presence of amino-acids, under the initial hydrolysis conditions has not been fully investigated. More than 98 per cent of the total nitrogen, as shown by the ninhydrin-positive components, was recovered from a protein-carbohydrate complex, which contained 8 per cent of hexosamines and more than 60 per cent of amino-acids, after 0.05 gm. was

hydrolysed with 10 ml. of 20 per cent w/w hydrochloric acid at 100° for 24 hr. It would thus appear that the amount of breakdown is small when a large excess of acid is used for hydrolysis.

Cleavage of the 2:4-Dinitrophenylhydrazones of Ketones

THE interesting contribution of J. Demaecker and R. H. Martin¹ on this subject prompts me to mention an alternative method which was devised in the course of work (1946) in the strychnine series.

The ketone 4-nitrophenylhydrazone or 2:4-dinitrophenylhydrazone was heated on the steam-bath with 80 per cent formic acid (or stronger) and copper carbonate added. The end-point was in most cases indicated by the disappearance of colour. In this process the nitro- or dinitro-phenylhydrazine produced by hydrolysis is destroyed by oxidation, and, however unfavourable the equilibrium between hydraxine and hydrazone may be, the liberation of ketone goes to completion. The method was found to be generally applicable, and the yields of ketone were high.

Preparation of Monodeuteriomethyl Bromide

THE exchange of deuterium and hydrogen has prevented the attainment of a high degree of isotopic purity in the preparation of compounds of the type CH_2DX , where X is a halogen atom or hydroxyl group. CH_2DOD has been prepared by the action of diazomethane on heavy water. Halford *et al.*¹ acidified the D_2O with SO_2 . No exact indication of the isotopic purity of the product was obtained². Langseth and Bak³ claimed that about 10 per cent CH_3OH was present in CH_2DOD prepared by the same method due to water unavoidably present in the CH_3N_2 . Beersmans and Jungers⁴ repeatedly bubbled gaseous CH_3N_2 through D_2O until reaction was complete. The product was a mixture of all the different isotopic forms. Without acidification the reaction may proceed by a free radical mechanism⁵ leading to exchange. The methyl bromide prepared by esterification with HBr (in which no exchange occurs) contained 51 per cent CH_2DBr and CHD_2Br ⁶.

I prepared CH_2DBr in about 93 per cent isotopic purity by the direct action of CH_3N_2 and DBr in dibutyl ether⁷. The reagents are difficult to handle on a large scale, and it does not seem possible to avoid exchange with such reactive materials.

CH_3DBr has now been prepared in high yield by the method:

Ketene was prepared in the standard way⁸ and bubbled directly through D_2O . The acetic anhydride, after fractional distillation, combined directly with dry Ag_2O . The method of Bockmuller and Hoffman⁹ was followed in the bromination.

Mass-spectrometric analysis indicated about 5 per cent CH_3DBr in the product. This agreed with the analysis of the anhydride and indicated that exchange did not occur in the last steps of the reaction.

Langeath and Bak⁸ prepared $\text{CH}_3\text{D.CO.OCH}_3$ in high isotopic purity by partial acid hydrolysis of dimethyl malonic ester in D_2O followed by decarboxylation of the resultant mono-ester. Silver acetate was prepared from the acid, and the methyl bromide produced by bromination as above was a mixture of CH_3Br , CH_3DBr , CHD_2Br and $\text{CH}_2\text{D}_2\text{Br}$. The exchange was presumed to occur in the last step.

In view of the above results, it is more probable that water, formed in the action of acetic acid on silver oxide, was exchanged with the methyl group of the silver acetate^{10,11}.

Properties of the Calcium Phosphates

WORKERS on the chemistry of soils and fertilizers have to deal with phosphorus compounds, many of which are complex or of indefinite composition. It is likely that, if fundamental information were available concerning these compounds of fairly well-defined composition, the transformations occurring during manufacture and after application to the soil might be more understandable.

The most widely used phosphate fertilizer is superphosphate, which consists mainly of monocalcium phosphate and calcium sulphate. It depends for its

production upon the use of large quantities of sulphuric acid. Past shortages and doubts concerning future supplies of this acid are among the reasons focusing attention on fertilizers containing more basic phosphates such as dicalcium phosphate, hydroxyapatite and materials of composition between these.

A co-operative programme of work has been commenced in these laboratories aiming in the first instance at establishing the structures of certain calcium phosphates and at developing laboratory techniques permitting an approximate evaluation of their agronomic value.

Fig. 1. A sheet of composition CaPO_4 in the structure of $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$

The structures being studied at present are those of $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$ and CaHPO_4 . A forecast that the former structure would be similar to that of gypsum has already been made¹, and we have confirmed the correctness of this by single-crystal X-ray methods.

The unit cell dimensions of $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$ are: $a = 5.812$, $b = 15.180$, $c = 6.239$ Å., $\beta = 116^\circ 25'$. These data correspond to a different choice of a -axis (and of β) from that used by Wooster for gypsum². Wooster's values were apparently taken from Onorato³. The space group of $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$ is $I 2/a$ and the cell contains four formula units. The Ca and P (and probably the H also) are on the two-fold axes, the y parameters of Ca and P differing by exactly a half. These positions of the heavy atoms enable a complete structure determination to be carried out by Fourier methods, and this work has now been almost completed.

In Fig. 1 (a projection along the b -axis), PO_4 groups are represented by oxygen atoms arranged tetrahedrally around the central phosphorus atom. The calcium atoms have six of their eight co-ordination positions occupied by oxygen atoms from PO_4 groups and the remaining two are filled by water molecules. The basic structure can conveniently be regarded as being built of sheets containing parallel chains of composition $=\text{PO}_4=\text{Ca}=\text{PO}_4=\text{Ca}=\text{}$. These run down from left to right in Fig. 1. Adjoining chains in any one sheet differ in height by 2.3 Å. to give a corrugation effect. The higher set of chains is related to the lower by centres of symmetry between the PO_4 groups and between the calcium ions of different molecules. The corrugated sheets themselves are repeated at a separation of $b/2 = 7.59$ Å. by vertical screw axes. Between the sheets are the water molecules, each molecule linking a calcium atom and an oxygen atom in one sheet to an oxygen atom in an adjacent sheet.

The minor differences between the structure of the $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$ and $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ are probably associated with the fact that the former is the hydrate of an acid salt. This work will be published in full elsewhere. Our thanks are due to the Research Department of the Tennessee Valley Authority for supplying some materials for this work

Ignition of Methane-Air Mixtures by Rapid Compression

In an earlier communication¹, the occurrence of bright blue flames by rapid adiabatic compression of methane-air mixtures was reported. Similar observations have recently been reported for methane by other workers^{2,3} using the motored engine technique.

In recent experiments we have improved our original method in which the compression ratio of the motored engine was increased to approach the ignition boundary. A machine of fixed compression ratio of 14.7:1 is now used with an accurately controlled preheat charge temperature. The charge temperature and the mixture composition can be varied with continuous observation of the ignition flame, and in this way the regions of reaction may be charted. The separate regions of blue and yellow flames are clearly distinguished in Fig. 1. It is seen that ignition boundaries have been established at mixture ratios far weaker than have previously been recorded by the motored engine method. A broad and stable region of blue flame has been discovered making possible spectroscopic observation of the light emission. These investigations are proceeding.

A study of the products of reaction has revealed an initial slow reaction for which no radiation has been detected and for which carbon monoxide appears as a delayed product. A boundary for the initial detection of carbon monoxide is shown as the line AB in Fig. 1. Continuous measurement of the composition of the products has shown that the carbon monoxide concentration increases very sharply as the blue ignition limit is approached and that a sharp drop in concentration occurs with the appearance of the blue flames. The lower blue flame boundary is sharp and very reproducible. A similar variation in the products of reaction of weak methane-air mixtures has been found by Burgoyne and Hirsch⁴ using an entirely different experimental method in which the mixture reacts when flowing through a heated tube. The carbon mon-

oxide formed by slow oxidation of the methane has been shown to oxidize rapidly at a sharply defined temperature.

In Figs. 2 and 3 simultaneous pressure and luminosity diagrams are given for typical blue and yellow ignitions. It will be seen that the yellow ignition reaction is early in the cycle and is marked by a steep pressure rise. The blue ignition, at the same temperature, but with a weakened mixture, occurs late in the cycle and shows a less steep rate of pressure rise. The corresponding luminosity diagrams were recorded with a gas-filled photo-cell using an Ilford Spectrum Violet Filter. It is seen that the blue radiation predominates in the yellow ignition flame.

The results now presented show that the blue ignition reactions of methane can occur at very lean mixtures under favourable temperature and pressure conditions. The exact nature of the two modes of ignition is still not clear. It is hoped that, since the cyclic regularity of both blue and yellow ignitions is satisfactory even close to the ignition boundaries, it will be possible to obtain emission spectra and thus elucidate the two mechanisms of ignition.

This work is supported by the Ministry of Fuel and Power.

Note added in proof, February 26. Spectroscopic studies in collaboration with Dr. A. G. Gaydon have now shown that the light emission in the blue region shows a strong continuum of burning carbon monoxide on which a well-defined banded structure is superimposed. This structure has been identified as that

Influence of Cation-Exchange Resins on Adenosine Triphosphate

CATION-EXCHANGE resins provide a convenient means of obtaining free acids from their salts, and the use of resins for obtaining adenosine triphosphate (ATP) from its barium salt has been described¹⁻³.

We have found that ATP which has undergone treatment by a cation-exchange resin behaves unexpectedly when chromatographed on paper. ATP was prepared from Ba₃ATP₄H₂O (Schwarz: New York) by shaking it in aqueous suspension with 'Amberlite IR-120(H)'. When chromatographed according to the method of Burrows, Grylls and Harrison⁴ (solvents 2, 4 and 7), the ATP was located in the position normally occupied by adenosine diphosphate (ADP). Similar anomalous *R_F* values were obtained when a barium salt prepared from ATP (free acid supplied by Light of Colnbrook) was shaken with 'Amberlite IR-120(Na)' or 'IR-100(H)'; or dissolved in acetic or formic acid and passed through a column of 'IR-120(Na)'.

In order to confirm that the resin was responsible for the increase of *R_F* value, aqueous solutions of ATP (Light) were shaken with 'IR-100(H)' or 'IR-120(Na)'. Increased *R_F* values were again found. Similar effects were obtained whether the treated ATP was applied to the paper directly or after evaporation (either as the free acid or in neutral solution) to small bulk at 0° C. under reduced pressure. Under the same conditions the *R_F* values of ADP and adenosine monophosphate were unchanged. Treated and untreated samples of ATP were normally run side by side on the same paper.

Solutions of ATP were prepared from the barium salt (Schwarz) by treatment with sulphuric acid and divided into two parts, one of which was shaken with 'IR-120(H)'. Electrometric titrations showed small significant differences between resin-treated and untreated solutions. Measurement at five-minute intervals of orthophosphate liberated by *N* acetic acid at 100° C. during two hours showed no difference in the hydrolysis-rates of resin-treated and untreated solutions.

A sample of ATP (Light), when chromatographed on paper, gave two well-separated bands, which on elution and analysis were found to have the appropriate total-to-hydrolysable phosphate ratios for

ATP and ADP respectively. The presence of both ATP and ADP in the sample had been previously confirmed by separation on an anion-exchange column according to the procedure of Cohn and Carter⁵. After treatment with 'Amberlite IR-120(H)' resin, paper chromatography of the same sample gave one band only, in the ADP position. When the material from this band was eluted, concentrated by evaporation at 0° C. under reduced pressure and rechromatographed, two bands appeared corresponding to ATP and ADP.

Analogous treatment of the ADP band from an untreated sample of ATP also produced a chromatogram with some material in the ATP position. It is suggested that some samples of ATP may therefore contain two forms of the compound having different characteristics.

Deoxypentose Nucleic Acid in the Expressible Fluid of Cod Fillets

WHEN fillets of fish are allowed to stand for some time under humid conditions, there is invariably an exudation of a cloudy fluid or 'drip'. If submitted to pressure, the fillets lose fluid ('expressible fluid') at a much faster rate. It has been observed by numerous workers that when the tissue is frozen there is an increase in both the 'drip' and the 'expressible fluid'. A method has been worked out in this laboratory for measuring the amount of 'expressible fluid' that can be obtained from whole fillets cut from fresh and frozen fish. The conditions that are employed are such that it is believed that no appreciable rupture of cells occurs during the time that the fillets are submitted to pressure, and that the exudate consists, therefore, almost entirely of intercellular fluid.

Since deoxypentose nucleic acid (DNA) is found only in cell nuclei, it seemed likely that if any were found in the 'expressible fluid' it would be indicative of cell rupture, with liberation of nuclear material into the interstices. Accordingly, DNA was determined in a large number of samples of 'expressible fluid' obtained from fish treated in different ways. The separation was accomplished with a modified Schmidt-Thannhäuser¹ procedure, and the DNA phosphorus was determined by the method of Berenblum and Chain².

It was found that the 'expressible fluid' from fresh undamaged fillets always contained some DNA (c. 0.12 mgm. DNA phosphorus per 100 ml.) which probably had its origin in nuclear material exuding from the severed cells at the cut surface of the fillets. This view was supported when a large number of fillets was allowed to drain on sloping trays for 24 hours in a saturated atmosphere, without applying pressure. More DNA (c. 0.4 mgm. DNA phosphorus

per 100 ml.) was found in the small quantity of 'drip' obtained than in the 'expressible fluid' from similar fillets. Thus the application of pressure released further fluid of lower DNA concentration, presumably intercellular fluid.

The effect of mechanical damage was illustrated by dividing some similar cod fillets into three groups. The first was pressed under the standard conditions for six hours, the second minced once through a domestic mincer, and the third 'minced' with a domestic mincer and the product put through a Latapie mincer. The two portions of mince were centrifuged at 3,500g for half an hour, and the supernatant fluid poured off. The concentrations of DNA phosphorus were respectively 0.124, 0.380 and 0.807 mgm. per 100 ml. fluid. These results suggest that, whereas the action of a domestic mincer is mostly a tearing apart of the muscle fibres, the Latapie mincer actually breaks the fibres up.

The effect of keeping cod on ice for several days before filleting was small. The DNA-level remained fairly constant from 2 to 9 days, and thereafter showed a small continuous rise, data being obtained up to 16 days. It is suggested that this small rise may be due to the synthesis of DNA by bacteria.

Striking results were obtained when the DNA content of the 'expressible fluid' of fish frozen at different rates was measured. Two effects were shown: (1) In a series of fillets that were frozen more and more quickly, DNA phosphorus levels rose very gradually (from c. 0.2 to 0.3) as freezing-rate increased, and then suddenly rose to a sharp maximum (0.6), falling again to a low level (0.2) as the rate increased further. Microscopic examination of the frozen fish indicated that this maximum corresponded with the entry of ice crystals into the muscle cells.

It has been known for some time that in slowly frozen muscle there are large ice crystals which form between the fibres, whereas in rapidly frozen tissue the crystals are small and within the fibres. This DNA maximum marks the change-over point, where the cooling is just rapid enough to produce intracellular crystals, but where the latter are so big that they rupture the sarcolemmas and liberate nuclear material. As the freezing-rate increases further, the size of the crystals diminishes, leaving the sarcolemmas intact.

(2) When the fillets were frozen very rapidly indeed, as in liquid oxygen and in CO₂-alcohol, there was a further rise in DNA phosphorus concentration to c. 0.5 mgm. per 100 ml. This rise was probably caused by a hard frozen layer forming around the fillet, which tended to prevent the inside from expanding when it froze later, thus setting up a sudden great internal pressure. Fillets frozen more slowly presumably retained a 'cheesy' consistency sufficiently long to permit accommodation to the stresses set up. A similar effect occurred in fillets packed tightly twelve deep in a box and frozen from two opposite faces. The fillets froze from the cooling surfaces towards the centre, and it was found that the fillets at the centre of the box, which were the last to freeze, and which in this instance froze at very slow rates, had high levels of DNA phosphorus in the 'expressible fluid' (c. 0.5 and 0.75 mgm. in two experiments). It is probable that damage to these fillets was caused by their expanding against the restrictions set up by the hard outer masses of the already frozen fish.

It should be emphasized that the fillets were all cooled to the same final temperature, whatever the

rate of freezing, and all were thawed under the same conditions.

It is commonly held that muscle tissue is damaged less and less the more rapidly it is frozen. The results described here indicate that this belief is too simple.

A full account will be published elsewhere.

A Bacterial Toxin paralyzing Silkworm Larvae

CERTAIN strains of *Bacillus cereus* are among the more virulent known bacterial pathogens of the silkworm, *Bombyx mori* L.¹ Toumanoff and Vago² isolated a strain of *B. cereus* (*B. cereus* var. *alesti*) which causes toxemia, a septicemia and intermediate conditions in silkworm larvae. Another strain of *B. cereus* (*B. cereus* var. *sotto*) was studied by Aoki and Chigasaki³, who suggested that its effect was due to a toxin. A culture of *B. sotto* was kindly made available by Mr. Masatake Ono, of Tokyo, and the disease caused by it has been under investigation in this laboratory since early in 1953.

The work of Aoki and Chigasaki³ has been confirmed. Two conditions have been observed in larvae infested with *B. sotto*: a profound paralysis 2 or 3 hr. after ingestion of old cultures and a septicemia without paralysis 12-24 hr. after injection of spores and cells into the body cavity. The rapid onset of paralysis, which took place without any discernible increase of the ingested bacteria, was suggestive of the presence of a pre-formed toxin; but no toxin could be demonstrated in culture media in which the bacteria had been grown.

It was found in our experiments that treatment of old cultures of *B. sotto* with clarified silkworm gut juice yielded a toxic extract. As silkworm gut juice is normally alkaline (pH 9.5-10.0), an old culture of *B. sotto* was treated with dilute alkali and filtered through a fritted glass filter. The sterile filtrate caused paralysis of silkworm larvae. Hannay⁴ has recently observed alkali-soluble crystalline inclusions in sporulating cells of strains of *B. cereus* known to be pathogenic for insect larvae. Microscopical examination of *B. sotto* revealed similar crystals. Treatment of a suspension of spores, crystals, and vegetative debris with alkali resulted in the dissolution of the crystals without affecting the viability of the spores.

An experiment was done to test whether there might be any foundation to the speculation made by Hannay⁴ that the crystals might be a toxic substance encouraging septicemia of the insect larvae. A suspension of crystals, spores and vegetative debris of *B. sotto* was well washed by centrifugation, resuspended in water, and divided into two parts. One part was diluted and tested against silkworm larvae both by injecting a quantity of it into the body cavity and by feeding. The second part was treated with alkali until the crystals had dissolved, then the spores and debris were centrifuged out, well washed by centrifugation and resuspended in water. A

THE EFFECT OF FEEDING AND INJECTING LARVAE OF *Bombus mori* L. WITH FRACTIONS OF AN ALKALI-TREATED CULTURE OF *B. sotto*

	Method of dosing larvae	
	By feeding	By injection
<i>Original culture</i> Spores and crystals (1×10^8 spores per larva)	Paralysis within 4 hr., septicemia within 12 hr.	Septicemia within 12 hr. No paralysis
<i>Alkali-treated culture</i> 1. Spore fraction (1×10^8 spores per larva)	No effect	Septicemia within 12 hr.
2. Supernatant	Paralysis within 4 hr. No septicemia	No effect
3. Supernatant dialysed	Paralysis within 4 hr. No septicemia	No effect
4. Supernatant heated at 70° C. for 30 min.	No effect	No effect

portion of the supernatant was dialysed against water and another portion heated at 70° C. for 30 min. All four fractions were tested by feeding and injection. The results are given in the accompanying table.

The results indicate that the septicemia following feeding is dependent upon the presence of a toxic substance which is heat-labile and non-dialysable. The toxin had a paralytic effect when fed but was non-toxic when injected. The crystal-free spores, on the other hand, were pathogenic when injected but non-invasive when fed.

By differential centrifugation of a suspension of spores and crystals, two fractions were obtained which differed significantly in the ratio of spores to crystals. It was found by feeding various dilutions of the two fractions that toxicity varied as the crystal count and was independent of the number of spores present.

The results presented above indicate that the toxic component in old cultures of *Bacillus sotto* responsible for paralysis in silkworm larvae is associated with the crystalline inclusions described by Hannay. The investigation of its nature and mode of action is being continued.

Buds on the Roots of the Rosebay Willow-herb (Fireweed)

SEVERAL investigators have previously recorded the presence of buds on the roots of the rosebay willow-herb or fireweed (*Chamaenerion angustifolium* (L.) Scop.)¹⁻⁴, and the purpose of the present work was to obtain a more complete picture of the formation of these root buds.

On the surface of the roots of *Chamaenerion* are small pit-like depressions. These depressions mark the position of the root traces on secondarily thickened roots in their first year of growth; but according to Moes⁵ in older roots with one or more interxylary periderms the depressions result from the disorgan-

Fig. 1. A root bud of *Chamaenerion angustifolium* (L.) Scop. in the proximity of a root trace (at X, but not entirely in the plane of the section). The bud has ruptured the outer tissues of the periderm. ($\times 75$)

ization of young buds and lateral roots. Buds and lateral roots originate within the proximity of these depressions, and in order to obtain a succession of stages in the formation of lateral roots and buds the depressions were first marked with indian ink and root cuttings, several centimetres long, grown in a constant-temperature room ($21^\circ \pm 1^\circ$ C.) on filter paper kept moist with distilled water. Every other day one or two cuttings were removed and microtome sections cut in the region of the depressions. Unfortunately, very early stages in bud formation could not be detected with certainty since the buds originated from tissues which were already meristematic. However, it has been found that they are endogenous in origin and arise from the external phellogen and its immediate derivatives (Fig. 1). Lateral roots also originate from the external phellogen and its immediate derivatives, and like the buds they are endogenous and rupture the outer tissues of the periderm as they emerge.

Fig. 2. Stages in bud formation at the distal cut surfaces of decapitated buds: (a) camera lucida drawing of initial activity involving cells just below the cut surface ($\times 527$); (b) the adjacent cells above the meristem have ruptured ($\times 120$); (c) later stage in bud formation ($\times 80$)

Root cuttings produced not only buds and roots but also small green hemispherical mounds. After a few days, shoots, a number of which were fasciated, and very occasionally roots, developed from these mounds. Microtome sections revealed that the mounds developed from the distal out surface of decapitated buds. The first indication of the formation of a bud meristem was seen in a group of deeply stained cells just below the surface of a mound. At this stage only a few cell layers were involved (Fig. 2a); but gradually the tendency to become meristematic extended inwards. As the meristem increased in size a tunica and corpus became distinguishable and ultimately the adjacent cells above ruptured, disintegrated and the meristem became freely exposed on the surface of the mound (Fig. 2b). Leaf primordia were later formed and prevascular strands differentiated downwards to the cambium of the decapitated bud (Fig. 2c). These buds are therefore endogenous in origin, as are the roots which very occasionally develop from these mounds. This contrasts with the origin of the shoot buds which are exogenous in *Chamaenerion*.

These findings are in agreement with those of previous investigators who have shown that, though occasionally endogenous, shoot buds of vascular plants are exogenous whereas root buds are endogenous¹⁻³, and the question arises as to the nature of the factors involved in determining whether a particular meristem becomes that of a root or a shoot. The results of some preliminary experiments indicate that auxins and wound hormones are involved in determining the future development of a meristem in the root cuttings of *Chamaenerion*, and further studies are being made along these lines.

I wish to express my gratitude to Prof. C. W. Wardlaw and Dr. A. Allsopp for their guidance and encouragement throughout this investigation, and to Mr. Ernest Ashby for the photographic illustrations.

Action of Peptone on Mast Cells of the Dog

ALTERATIONS of mast cells in the liver of dogs submitted to peptone shock were described by Wilander¹; Jaques and Waters² have confirmed Wilander's results and found similar changes of the mast cells in anaphylactic shock. These alterations have been related by these authors to heparin liberation.

Riley and West³ and Riley⁴ observed a striking correlation between mast cells content of a tissue and its concentration of histamine. In addition, Riley⁵ and we⁶ verified disruption of mast cells in conditions in which histamine liberation occurs. These papers suggest that mast cells might be a source of histamine in animal tissue.

Recently, Lecomte and Baecckeland⁷ could not duplicate Wilander's findings, observing no changes in dog liver mast cells after peptone shock. Our recent experiments support Wilander's results.

The effect of peptone on the mast cells was studied in ten dogs injected intravenously with 0.5 gm. per kgm. of peptone, in which blood pressure and clotting time were determined. Liver biopsies were made before and after the peptone shock. Experiments performed in order to obtain an adequate technique for the preservation of dog mast cells showed that aqueous fixatives and paraffin embedding must be avoided. Good results were obtained only with a 4 per cent solution of lead sub-acetate in 50 per cent alcohol, and this was used throughout. Frozen

Chromosome Numbers in British *Salicornia*

COUNTS so far obtained of the chromosomes of *Salicornia* species indicate the basic number $x = 9$. British material examined from localities on the estuary of the River Medway has yielded the following counts: *Salicornia perennis* Mill. var. *radicans* Moes and Salisbury in "Camb. Brit. Fl.",¹ $2n = 18$; *Salicornia ramosissima* Woods, form agreeing closely with the habit illustration in "Camb. Brit. Fl.", $2n = 18$; dwarf red form, $2n = 18$; *Salicornia stricta* Dum. sec. Moes, form agreeing closely with the illustration in "Further Illustrations of British Plants"² of *S. europaea* L., $2n = 36$; *Salicornia dolichostachya* Moes, erect form with long tapering fertile branches; upper nodes each bearing

Fig. 1. Mast cells in the connective tissue of dog's tongue, using Ehrlich's thionin stain ($\times 800$). (A) from control animal; (B) from dog after peptone shock. Note degranulation and reduction of metachromasia of remaining granules.

sections, 50 μ thick, stained by Ehrlich's thionin, were studied. In these conditions, not only Wilander's observations concerning the effect of peptone shock on liver mast cells could be confirmed, but it was also observed that mast cells of other organs (tongue, spleen, mesentery, lung, etc.) presented identical changes. In the tongue, an organ particularly rich in mast cells, these changes are easily observed (Fig. 1). Peptone shock induces a significant decrease in the number of mast cells and promotes a degranulation and reduction of metachromasia of the remaining granules. These alterations seem to depend on the local concentration of peptone, since we have observed that when the peptone solution is injected directly into the lingual artery the mast cells of this organ present exceptionally intense changes. This fact, and our observations that mast cells of other organs also present alterations, suggest that in the dog, heparin and histamine might originate from other organs besides the liver. A detailed account of these results will be published.

range 6.8-7.2 are optimal. The effect is entirely abolished by 0.3 mM calcium chloride. Over a wide range the activity of the preparations as myokinase and their activity as a relaxing factor go hand in hand. The evidence suggests, however, that in its role as relaxing factor myokinase is acting in a way which cannot be explained simply in terms of its ability to resynthesize adenosine triphosphate, and that it probably takes part in a more complex reaction, when actomyosin and the adenosine nucleotides are present.

Thus, the effect of the original factor of Marsh can be explained in terms of its myokinase activity; but it is quite out of the question to explain it in terms of creatine phosphokinase, since (a) the conditions of preparation and use of the factor preclude the possibility of the presence of creatine phosphate in the system; and (b) the effect is optimal in the normal physiological pH range, 6.8-7.2, and is diminished in the range 6.0-6.5.

The work described in this paper was carried out as part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research.

Myokinase as a Relaxing Factor in Muscle

LORAND¹ has recently shown that relaxation of muscle-fibre models will occur when 10 mM creatine phosphate, 5 mM adenosine triphosphate and an enzyme preparation of muscle are added to them. The enzyme (adenosine triphosphate-creatine transphosphorylase) is probably identical with Lohmann's enzyme, creatine phosphokinase². Relaxation occurs only at low pH (6.2 or below), whereas the fibres shorten or develop tension at higher pH values. Magnesium ions (1 to 2 mM) are necessary for the relaxation which is inhibited by calcium ions. Lorand suggests that the effect is due to resynthesis of adenosine triphosphate, as fast as it is broken down by the fibres, by virtue of the reaction:

This is known to go to the right at pH values below 6.5³. He suggests further that any system capable of resynthesizing adenosine triphosphate would act in the same way and, in particular, that myokinase would do so, since it catalyses the reaction:

I have, in fact, been able to show, in a paper submitted for publication in December of last year⁴, that myokinase does indeed bring about relaxation of muscle-fibre models, and that it is indistinguishable in its effect from the relaxing factor of Marsh⁵. For full-activity magnesium ions (4 mM), an ionic strength between 0.10 and 0.20, and a pH in the

Coenzyme of Kidney Phosphatase

In previous communications¹ we advanced a hypothesis supporting the nucleotide nature of kidney phosphatase. Kutscher and Schreier² also consider phosphatases as metal proteins, and they attribute the loss in activity which they display on dialysis not only to the elimination of magnesium, but also to the separation of another substance which Kutscher and Sieg³ designate as choline pyrophosphate. In their turn, Akamatsu and Kobayashi⁴ regard histidine as a coenzyme. Recently, however, investigating intestinal phosphatase preparations purified by paper electrophoresis, Roche considers⁵, in view of the results obtained in his analyses, that the hypotheses advanced on the nature of cophosphatase (nucleotide, choline pyrophosphate or histidine) are scarcely probable.

So far as we are concerned, the results obtained in the course of recent experiments still support our interpretation. As a matter of fact, the phosphatase by extraction with trichloroacetic acid, in order to separate the protein portion, and subsequent hydrolysis with baryta, gave solutions which were chromatographed on Whatman No. 1 paper with the object of characterizing the nucleotide. We employed the 2 N HCl-isopropanol mixture which Wyatt recommends⁶ and developed the chromatogram in the presence of ultra-violet light, employing a quartz lamp fitted with a Corning 9863 filter (240-400 m μ). A spot, the R_F of which is close to that of uridylic acid, was thus obtained. Once that portion of paper which

Fig. 1. Absorption curves: ●—●, phosphatase; ○—○, uridylic acid (Plesser and Loring, *J. Biol. Chem.*, 178, 431; 1949)

corresponds to the phosphatase spot in the chromatogram had been separated we obtained, after eluting with 0.01 N HCl, the spectrum shown in Fig. 1 (with a maximum of 261 mμ), falling in with that of uridylic acid, which appears superimposed.

It is evident that, despite this result, the lack of a purity guarantee in the phosphatase preparation we employed is a factor of a weight sufficient to prevent us from affirming that uridylic acid is a component of the former. In order to ascertain, in so far as feasible, its participation in the structure of phosphatase, we proceeded to inoculate rats and rabbits with a precursor of uridylic acid, orotic-2-¹⁴C acid¹, with the object of investigating the possible presence of ¹⁴C in the kidney phosphatase of the inoculated animals as well as its relationship to enzymatic activity. The results obtained are reproduced in the accompanying table.

The results reveal that a variation in the enzymatic activity of the preparation (percentage P) is attended by a variation in counts/min. practically

No of experiment	Phosphatase preparation	Radioactivity		Enzymatic activity	
		c./m.	% Δ	% P hydrolysed	% Δ
1	a	1,370		19.8	
	a ₁	1,900	35	27.8	35
	b	inestimable		0.64	
2	a	1,430		24.8	
	a ₁	2,000	39	33.8	36
	b	420	-80	4.9	-85

a, According to Albers².

a₁, According to Albers² purified by reprecipitations with acetone.

b, Precipitated by alcohol from the enzymatic solution after separating a.

checking in percentage. This permits us to attribute both effects to the same substance.

Once the radioactive phosphatase has been hydrolysed under conditions identical with those in previous experiments and the chromatogram developed, the portion of paper corresponding to the uridylic acid stain was cut away while the rest of the chromatogram was cut into several pieces. All these were eluted with 0.01 N HCl before evaporating to dryness and counting in the Geiger-Müller counter. As Fig. 2 shows, the portion corresponding to uridylic acid displayed a marked radioactivity, and only that part contiguous to it was radioactive but in a much lesser scale. The protein fraction separated by trichloroacetic acid displayed no radioactive activity at all. All the carbon-14 in phosphatase is therefore present in uridylic acid. As, on the other hand, the table permits us to refer enzymatic activity to this same substance, it seems probable that uridylic acid is a component of kidney cophosphatase.

X-Ray Analysis of the Structure of Peripheral Nerve Myelin

THE low-angle diffraction pattern of fresh sciatic nerve of frog takes a relatively simple form, showing only six equatorial reflexions, five of which can be accounted for as successive orders of diffraction from a radially oriented fundamental structural unit measuring 171 Å.^{1,2} These five reflexions display striking variations in intensities as indicated in Fig. 1a, and from this intensity data a Patterson distribution (variation of $P = F^2_{(hkl)} \cos 2\pi ls$) along a line in the radial direction in the sheath has been calculated (Fig. 1a).

In earlier experiments on the modification of nerve myelin³⁻⁵, it was observed that a relatively slight drying of the nerve specimen produced a marked increase in the intensity of the third-order diffraction and a decrease in the intensities of the higher orders.

Fig. 2. Counting of chromatogram. Horizontal axis of histogram is in cm.

Fig. 1. Low-angle diffraction data and corresponding one-dimensional Patterson distributions for (a) fresh frog sciatic nerve; (b) nerve immersed in Ringer's solution of ten times normal concentration for twenty-four hours; (c) suggested general scheme of molecular organization within the unit cell of fresh peripheral nerve myelin indicating levels A and B at which peak electron densities might be expected. The approximate positions of phosphate groups in phospholipid molecules are marked with the letter P.

These changes were accompanied by a small reduction (c. 5–6 Å.) in the fundamental spacing, and were reversible. A similar effect (Fig. 1b) was obtained under more readily controllable conditions by immersing the nerve in Ringer's solution of greater than normal concentration⁴.

The net effect on the Patterson diagrams of this modification is to replace the interaction at a quarter by a much stronger interaction at one-third of the unit cell dimension.

Other modifications^{2,5} of the nerve myelin were found to lead eventually to the disappearance of the odd orders of diffraction. Such modifications were irreversible.

In spite of the apparent chemical complexity of myelin, it is possible that the striking diffraction effects observed have a relatively simple explanation in terms of the general arrangement of molecules within the unit cell and the specific placing of a few atoms or groups of atoms of outstanding diffracting power. In previous considerations of the structure of myelin^{2,7,8}, molecular arrangements based on an alternation of lipid layers and protein layers have been suggested which would account for the tendency towards 'halving' in the 171-Å. dimension of the unit cell. The observations on the changes in pattern accompanying slight dehydration seem to be explained most readily on the general assumption that two sets of closely spaced groups of high diffracting power are responsible for the interactions, one set being separated by a quarter in the fresh myelin and the second set by a distance just greater than one-third. The shrinkage of the fundamental structural unit in the initial reversible stage of drying may be sufficient to reduce the separation of the first set of groups so

that they can no longer reinforce the fourth-order diffraction, and at the same time to bring the second set of groups into a position for reinforcing the third and sixth orders.

A recent suggestion of a detailed spatial arrangement of phospholipid and cholesterol molecules in the lipid layers of myelin^{9,10} immediately indicates two sets of levels at which peaks in the electron density distribution in the radial direction might be expected. These peaks are associated in part with the phosphate groups of the phospholipids which, in a lipoprotein structure consisting mainly of carbon, nitrogen, oxygen and hydrogen, might be expected to provide centres of outstanding electron density. Fig. 1c shows a schematic arrangement of components in the unit cell of nerve myelin in terms of which it is possible to give a qualitative explanation of the intensities of the various reflexions. For simplicity, the positions of the electron density peaks have been made identical in the two parts of the unit cell, and therefore different 'scattering factors' must be given to these levels to account for the intensities of the odd orders of diffraction. The longest phospholipid molecules are associated with the cholesterol in such a way that the phosphate group (P) of the former is brought into close association with the protein at the interface A, which may also contain metallic ions. This interface would thus be expected to provide one of the levels of high electron density, and is suggested to occur at or near $0, \frac{1}{4}, \frac{1}{2}$ and $\frac{3}{4}$ in the unit cell of slightly dehydrated myelin. With the type of spatial arrangement of phospholipid and cholesterol molecules shown in Fig. 1c a second level of high electron density might be expected to occur in the lipid layer at a distance of about 4–6 Å. from the interface, where the terminal groups of the curled phospholipid molecules come into association with the cholesterol, and in the case of phosphatidyl serines possibly also with metallic ions. The phosphate groups of any fully extended phospholipid molecules would also be expected to occur at this level, B, which is suggested to be at $0, \frac{1}{4}, \frac{1}{2}, \frac{3}{4}$ in the unit cell of fresh myelin.

Rough Fourier calculations have indicated the possibility of obtaining the right sequence of intensities for the various orders of diffraction in terms of these sets of electron density peaks; but two main factors hinder the detailed quantitative correlation. The molecular picture is not yet sufficiently detailed to permit the reliable prediction of the relative heights of the suggested electron density peaks, and the correction factors which must be applied to the measured intensities from this type of liquid crystalline system are not yet known.

FORTHCOMING EVENTS

(Meetings marked with an asterisk * are open to the public)

Monday, March 22

BONE AND TOOTH SOCIETY (at the Institute of Orthopaedics, 234 Great Portland Street, London, W.1), at 5 p.m.—Symposium on "Hereditary Skeletal Disease". Prof. L. S. Penrose: "Genetics and Bone Disease"; Dr. H. Grönberg: "Genetics and Bone Disease in Animals"; Dr. H. Harris: "Genetics of Rickets and Osteomalacia".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—Mr. J. F. M. Middleton: "Oxford University Expedition to Uganda".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at Darford Technical College, Lowfield Street, Darford, Kent), at 7.30 p.m.—Dr. J. M. Fletcher: "Chemical Problems Associated with Nuclear Reactors".

Monday, March 22—Friday, March 26

CERA FOUNDATION FOR THE PROMOTION OF INTERNATIONAL CO-OPERATION IN MEDICAL AND CHEMICAL RESEARCH (at 41 Portland Place, London, W.1).—Symposium on "The Chemistry and Biology of Pteridine".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.0.2).—Bicentenary Celebrations.

Tuesday, March 23

INSTITUTE OF FUEL (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Dr. H. Heywood: "Solar Energy for Water-and-Space-Heating".

UNIVERSITY OF LONDON (in the Anatomy Theatre—Communication Research Centre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Sir Geoffrey Vickers: "Communication in Economic Systems".

INSTITUTE OF ELECTRICIAL ENGINEERS, EDUCATION DISCUSSION GROUP (at Savoy Place, London, W.C.2), at 6 p.m.—Mr. F. A. Meier: "An Experimental and Theoretical Approach to the Teaching of Electromagnetism using the Rationalized M.K.S. System of Units".

SOUTH PLAINS ETHICAL SOCIETY (at Conway Hall, Red Lion Square, London, W.C.1), at 7.30 p.m.—Dr. J. Bronowski: "The Fulfilment of Man" (Conway Memorial Lecture).

Wednesday, March 24

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Sir Ben Lockspeiser, F.R.S.: "Manufactures, 1754-1954". (Special Bicentenary Lecture.)

PHYSICAL SOCIETY, COLOUR GROUP (at the Institute of Ophthalmology, Judd Street, London, W.C.1), at 3.15 p.m.—Fourteenth Annual General Meeting. 3.30 p.m.—Miss P. W. Trezona: "Additivity of Colour Equations". Dr. G. S. Brindley: "The Number of Kinds of Human Retinal Receptors and the Spatial and Temporal Summation and Resolution allowed by their Pathways".

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. Colin Clark: "World Supply and Requirements of Farm Products".

ENGINEERS SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. J. M. Tanner: "Physique and Choice of Career".

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP—NUTRITION PANEL (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.15 p.m.—Annual General Meeting.

ROYAL INSTITUTE OF CHEMISTRY (Joint meeting with the LONDON SECTION of the SOCIETY OF CHEMICAL INDUSTRY, at the Institute of Metals, Grosvenor Gardens, London, S.W.1), at 6.30 p.m.—Prof. A. B. J. P. Ubbelohde, F.R.S.: "Some Recent Advances in Physical Chemistry".

WOOD EDUCATION SOCIETY (at the Royal Institution, 21 Albemarle Street, London, W.1), at 7 p.m.—Sir John Lennep: "Growing Wood in Victoria".

CHADWICK PUBLIC LECTURE (in collaboration with the Leeds City Council, in the Museum Lecture Theatre, Park Row, Leeds 1), at 7.30 p.m.—Prof. S. B. Finer: "Edwin Chadwick and the Conquest of Disease 1843-1953".

Wednesday, March 24—Friday, March 26

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMERS GROUP (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2).—Symposium on "The Chemistry and Physics of Synthetic Fibres".

Thursday, March 25

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. G. R. Goldsbrough, F.R.S.: "Wind-effects on the Motion of the Sea in an Infinite Channel and in a Rectangular Gulf"; Mr. N. M. Bider: "Bddy Diffusion of Momentum, Water Vapour and Heat Near the Ground".

INSTITUTE OF MECHANICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. F. L. Lawton: "The Kamano Hydro-Electric Development and Associated Kinmat Aluminium-Reduction Works".

TELEVISION SOCIETY (at the Cinematograph Exhibitors' Association, 164 Shaftesbury Avenue, London, W.C.2), at 7 p.m.—Mr. R. J. Boddy and Mr. O. D. Gardner: "An Industrial Television Channel".

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Prof. H. J. Smolens, F.R.S.: "Organometallic Compounds Containing Fluorocarbon Radicals" (Liveridge Lecture).

Thursday, March 25—Friday, March 26

NATIONAL ASSOCIATION FOR MENTAL HEALTH (at Friends' House, Euston Road, London, N.W.1), at 10 a.m. daily—Annual Conference—"Strain and Stress in Modern Living: Special Opportunities and Responsibilities of Public Authorities".

Friday, March 26

INSTITUTE OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 10.30 a.m.—Conference on "Hydraulic Mechanisms".

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Geophysical Discussion. Speakers: Dr. J. M. Bruckshaw, Dr. A. H. Cook, F.R.S., Sir Harold Jeffreys, F.R.S., and Dr. S. K. Runcorn. Chairman: Dr. R. Stonley, F.R.S.

PHYSICAL SOCIETY (at the Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Sir Geoffrey Taylor, F.R.S.: "Diffusion and Mass Transport in Tubes" (38th Guthrie Lecture).

ROYAL INSTITUTE (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. F. A. Paneth, F.R.S.: "The Chemical Exploration of the Stratosphere".

Saturday, March 27

BRITISH SOCIOLOGICAL ASSOCIATION (in the Herringham Hall, Bedford College, Regent's Park, London, N.W.1), at 4.30 p.m.—Prof. W. J. H. Sproul: "Theory and Practice".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (with good university degree or equivalent, with considerable teaching and industrial or research experience) in AIRCRAFT STRUCTURES, to teach to Final B.Sc. and H.N.O. standard.—The Principal, Royal Aircraft Establishment Technical College, Farnborough, Hants (March 26).

LECTURER IN PHYSICS—The Secretary, Brickbeek College, Malet Street, London, W.C.1 (March 26).

METALLURGIST (with an honours degree in metallurgy and some experience in metallurgical research, and preferably with experience in the use of X-ray equipment) at the B.I.S.R.A. Laboratories in Swansea.—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1 (March 26).

COAL CHEMIST (Scientist Grade I) (with first- or second-class honours degree in chemistry, fuel technology or related subjects, and substantial experience of research in the above field) to lead research on the carbonization properties of coal used for smokeless fuel manufacture, Ref. TT/745; **SCIENTIST** (with good honours degree or equivalent, and preferably with general experience in coal chemistry and spectroscopic techniques), for work in the Chemistry Department in connection with infra-red and ultra-violet spectroscopy, Ref. TT/746.—The National Coal Board, Central Research Establishment, Stoke Orchard, near Cheltenham, Glos, quoting appropriate Ref. No. (March 27).

SCIENTIST in the Scientific Department of the London Headquarters of the National Coal Board, for work mainly in the hydraulic and mechanical fields, and will include the planning of large-scale experiments and the co-ordination of research data in forms suitable for use by engineers.—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/747 (March 27).

SENIOR LECTURER and a **LECTURER IN PHYSICS** at the University of Natal, Pietermaritzburg, and a **LECTURER IN PHYSICS** at the University of Natal, Durban.—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, April 7).

ASSISTANT COAL SURVEY OFFICER (with a good honours degree, or equivalent, in chemistry or fuel technology, and preferably with experience in industry, laboratory control, and the critical assembly of scientific data) at the Coal Survey Laboratory, Sheffield.—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/764 (April 10).

MATHEMATICIANS, Scientific Officer, Experimental Officer and Assistant Experimental Officer grades, in Ministry of Supply Research and Development Establishments, mainly in Southern England, for work including research into aerodynamics and aircraft structures, high speed electronic computers, radio and radar, including aerial design and radiation problems, engineering problems, and trials work requiring good practical outlook.—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting AS/54/A (April 14).

SOIL PHYSICIST (graduate who has received training in a recognized Soil Physics Laboratory, or with postgraduate experience in soil physics work, and preferably with experience in soil problems connected with irrigation) at the Sabi Valley Experimental Station, Department of Agriculture, Southern Rhodesia.—The Secretary, Rhodesia House, 439 Strand, London, W.C.2 (April 15).

ANALYST in the DEPARTMENT OF AGRICULTURE.—The Registrar, The University, Leeds 2 (April 10).

READER IN VETERINARY BIOCHEMISTRY at the Royal Veterinary College.—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 20).

CHAIR OF CHEMISTRY in University College, Dundee.—The Secretary, University of St. Andrews, College Gate, St. Andrews (April 30).

LECTURER IN BIOCHEMISTRY—The Secretary, Queen's University, Belfast (April 30).

LECTURER (with degree in metallurgy, engineering or related science) in INDUSTRIAL METALLURGY.—The Registrar, The University, Edgbaston, Birmingham 15 (April 30).

PEDOLOGIST or ASSISTANT PEDOLOGIST (with a good degree in science or agriculture or equivalent, and ability to express ideas in written work) at the Soil Bureau, Department of Scientific and Industrial Research, New Zealand, for soil surveys in New Zealand, and possibly for short-term secondment in the Pacific Islands—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting 3/64/142 (April 30).

RESEARCH OFFICER (graduate in physics, mechanical engineering, physical chemistry, or chemical engineering, and preferably with some experience of research in the preservation, processing and transport of food, preferably fish) at the **FISHING INDUSTRY RESEARCH INSTITUTE**, Cape Town, South Africa—The Secretary, P.O. Box 1233, Cape Town, South Africa (April 30).

SENIOR LECTURER IN ADULT EDUCATION at the University of New England, Armidale, New South Wales, Australia, to organize and administer tutorial classes, discussion groups, and other general adult education activities in northern New South Wales as may be required by the Council of the University—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Armidale, April 30).

SENIOR LECTURER or LECTURER (university graduate, or chartered mechanical engineer, and with some years of industrial experience in a design office) in **MACHINE DESIGN**, in the Department of Mechanical Engineering, University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, April 30).

HIGHLY MISCELLANEOUS RESEARCH FELLOW IN AERONAUTICS, for post-graduate research into problems of vibration or stability and control of aircraft—The Warden, College of Aeronautics, Cranfield, Bletchley, Bucks (May 1).

CHAIR OF CHEMICAL PATHOLOGY in St. Mary's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 3).

CHAIR OF PHYSICAL CHEMISTRY tenable at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 5).

CHAIR OF PHYSIOLOGY tenable at Queen Elizabeth College—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 6).

ASSISTANT BOTANIST (preferably with experience in microscopy, and with mathematical ability) in the **POMOLOGY SECTION** for work on plant anatomy—The Secretary, East Malling Research Station, near Maidstone, Kent (May 17).

PRISING SCHOLAR (preferably honours graduate, or final year undergraduate in engineering, mathematics or physics) in **AERONAUTICS**—The Warden, College of Aeronautics, Cranfield, Bletchley, Bucks (June 1).

DEMONSTRATOR IN ORGANIC CHEMISTRY and **DEMONSTRATORS IN INORGANIC CHEMISTRY**—The Registrar, The University, Nottingham. **LECTURER AND ASSISTANT PROFESSOR IN THE DEPARTMENT OF BACTERIOLOGY** at the Hebrew University of Jerusalem—Prof. Samson Wright, Middlesex Hospital, London, W.1.

LECTURER (with a university degree in agriculture, preferably with knowledge of tropical agriculture, and some teaching experience) in **AGRICULTURE**, at the College of Agriculture, Mauritius—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting ODB.63/52/06.

MASTER (with first-class honours degree, preferably Oxford or Cambridge) to **TEACH BIOLOGY** up to University Scholarship standard—The Headmaster, Haberdashers' Aske's Hampshire School, West-bere Road, London, N.W.2.

PHYSICIST (with a degree in physics, and capable of applying experimental techniques to the solution of fund problems in the iron and steel industry) in the **FLUID DYNAMICS SECTION** of the Physics Department in London—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

RESEARCH SCIENTIST (with B.Sc., preferably in physics) for research on domestic heating—The British Coal Utilization Research Association, Randaile Road, Leatherhead, Surrey, quoting A.2.

SCIENTIFIC OFFICER (with an honours degree in science, preferably physics, with postgraduate course, or equivalent experience in meteorology) at the **ROYAL OBSERVATORY**, Hong Kong, for forecasting, general meteorology, research, etc.—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting ODB. 57/51/03.

SCIENTIFIC OFFICERS (with first- or second-class honours degree in chemistry or equivalent) and **EXPERIMENTAL OFFICERS** (with at least H.S.C. (science) or equivalent) to undertake research involving the study of various physical and electrical properties of solid inorganic chemical materials, and their behaviour in ceramic applications—The Administrative Officer, Recruitment, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 40/W.G.R.

THE WORLD OF BEES

GILBERT NIXON

With 16 pages of line drawings
by Arthur Smith

This book gives a glimpse of bees in all their fascinating diversity of habit and behaviour. Mr. Gilbert Nixon, a famous entomologist, depicts the whole world of these extraordinary creatures—their social habits, their "language," courtship, and their now famous dances, in fact, every aspect of bee life. Crammed with facts. A must for every beekeeper. "A fascinating book, full of intriguing information and written with a personal enthusiasm which is infectious."

NESTA PAIN.

Published by Hutchinson at 12s. 6d.

The common test of tincture of soap

"Dr. Clark then exhibited his method of ascertaining quantitatively the comparative hardness of water by means of the common test of tincture of soap, illustrated by experimental evidence, to prove the accuracy of which it is susceptible and the facility of its application."

Dr. Clark gave his demonstration at one of the first meetings of the newly formed Chemical Society in 1841, and the above is an abstract from Volume I of the Proceedings.

The B.D.H. catalogue still includes Clark's Soap Solution and testifies to the remarkable permanence of his technique. Greater accuracy and convenience in total hardness determination, however, are now obtained from the B.D.H. Hardness Solutions and Indicator based on the use of ethylenediamine-tetracetic acid as advocated by Schwarzenbach and others.

LECTURES AND COURSES

SIR JOHN CASS COLLEGE

JEWRY STREET, LONDON, E.C.3

Telephone No.: ROYAL 3383

The College prepares students by full-time and by part-time day and evening courses in Botany, Mathematics, Chemistry, Physics, Geology, and Zoology for the Intermediate Examination and the B.Sc. General Degree of the University of London for internal and external students and for professional examinations. Full-time and part-time courses are also held for the B.Sc. Internal Special Degrees in Mathematics and in Physics, and for the B.Sc.(Eng.) Metallurgy Degree. There are full-time courses for the London Internal Special Degree in Chemistry and for the External Special Degrees in Botany and in Zoology. Facilities are provided for research and post-graduate study, and short courses of lectures are held on a variety of special topics.

Applications for enrolment for the academic year, 1954-55, may now be made on forms to be obtained from the Secretary.

ROYAL TECHNICAL COLLEGE

SALFORD

Principal: P. F. R. Venables, B.Sc., Ph.D., F.R.I.C.

DEPARTMENT OF PURE AND APPLIED PHYSICS

A short postgraduate course on Semi-conductors will be held on Friday, May 21, and Saturday, May 22, 1954. Lecturers: Professor F. A. Vick, O.B.E., Ph.D., F.Inst.P., H. J. Clark, B.A., J. A. F. Cormack, B.A., A.Inst.P., W. Needham, M.Sc., M.I.B.E., F.Inst.P., H. V. Shumner, M.Sc., Ph.D., D. D. Jones, M.Sc., D.I.C., D. A. Wright, M.Sc., F.R.A.S., F.Inst.P. Fee for the course, £1 10s 6d.

Forms of application, giving brief details of the lectures, may be obtained from the Head of Department, W. G. Darvell, M.Sc., F.Inst.P., Royal Technical College, Salford.

H. H. TOMSON,

Clerk to the Governors

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 to 64 inclusive, or a woman aged 18 to 59 inclusive, unless he or she, or the employment, is exempted from the provisions of the Notification of Vacancies Order, 1952.

SABI VALLEY EXPERIMENTAL STATION

DEPARTMENT OF AGRICULTURE

SOUTHERN RHODESIA

SOIL PHYSICIST

Applicants, under 36, must be graduates who have received training in a recognized soil physics laboratory or who have had postgraduate experience in soil physics work. Experience of soil problems connected with irrigation advantageous, but not essential. Starting Salary Scale: £624 by £90 to £904 by £45 to £1,074 by £120 to £1,194 by £48 to £1,482 per annum. Actual starting point, up to £984 per annum, depends on academic qualifications and experience. Allowances: Marriage £50 per annum, children's £60 per annum first, £24 per annum each other dependent child. Accommodation: A house will be available at reasonable rental.

Application forms and further details from the Secretary, Rhodesia House, 429 Strand, London, W.C.2. Completed forms to be returned by April 15, 1954.

BIRKENHEAD EDUCATION COMMITTEE

BIRKENHEAD TECHNICAL COLLEGE

Applications are invited for the following additional appointments to the full-time teaching staff: Science: (a) Lecturer in Organic Chemistry; (b) Lecturer in Physical and Inorganic Chemistry; (c) Assistant (Grade B) in Physics; (d) Assistant (Grade B) in Biology; (e) Assistant (Grade B) in Chemistry.

Further details and form of application can be obtained on receipt of stamped, addressed envelope (stating post) from the undersigned, to whom completed applications should be returned not later than April 2, 1954.

H. GLYN WILKINSON,

Director of Education.

Education Offices,
63 Hamilton Square,
Birkenhead

SHORT SERVICE COMMISSIONS IN THE INSTRUCTOR BRANCH OF THE ROYAL NAVY

Applications are invited from university graduates and qualified teachers under 36 years of age for short service commissions of three, four or five years in the Instructor Branch, Royal Navy. Applications will also be accepted from final year undergraduates, and these will be considered in anticipation of their degree results. Requirements are mainly for officers with qualifications in mathematics, science (physics, chemistry, metallurgy) or engineering, but a few vacancies exist for officers with qualifications in history or English, with a sound mathematics or science background. After two years' service, officers will be eligible for selection for permanent commissions. A short service engagement in the Instructor Branch will discharge any candidate's obligation under the National Service Act. Entry will be in two grades. Selected candidates with first- or second-class honours degrees receive approximately £410 in their first year's service, £429 in second year, £548 in third and fourth years, £584 in fifth year. Other candidates receive £319 in first, £392 in second and third years, £429 in fourth and fifth years. Previous officer service will be recognized for adjustment of seniority and rate of pay on entry. Accommodation and rations are provided or allowances in lieu. Married officers, if aged 25 or over, receive marriage allowance of £338 per annum if not accommodated in official married quarters, £283 per annum if they are so accommodated. Married officers under the age of 25 receive marriage allowance of £146 per annum, but are not entitled to be accommodated in official married quarters. An initial outfit allowance of £115 is paid, together with a free issue of certain articles of clothing. A reduced allowance is payable to candidates with previous Naval Service as officers. Tax-free gratuities of £300, £400 or £500 are payable at the end of three, four or five years respectively. Instructor officers serve both ashore and afloat, and their duties include both technical instruction and general education. Officers with suitable qualifications may also be trained and appointed for full- or part-time meteorological and weather forecasting duties. Service in the Instructor Branch will, in the case of officers who enter from a contributory service under the Teachers' (Superannuation) Act, be treated as contributory service, contributions being deducted from the above gratuities. Other officers may have their service in the Instructor Branch similarly treated if they so desire.

Fuller details and application forms may be obtained from Director (P), Naval Education Service, Admiralty, London, S.W.1. Completed application forms should be returned, if possible, before May 31, 1954.

H.M. COLONIAL SERVICE

Applications are invited for the following post: West African Fisheries Research Institute, Sierra Leone. A vacancy exists for a Biochemist. Candidates must be male and possess at least a good second-class honours degree, with appropriate postgraduate experience. Appointment either on probation in the Colonial Research Service with superannuation under contributory superannuation scheme, or on temporary terms with eventual gratuity of 15 per cent of salary. Salary in Scientific Officer scale (£400 to £650 per annum), plus overseas research allowance of £145 to £175 per annum. Cost-of-living allowance at present 27½ per cent of first £200 of basic salary, 25 per cent of next £400 and 12½ per cent of remainder (maximum £200 per annum), also payable. Outfit allowance £60 on first appointment. Free passages on appointment and leave for officer, wife and children under 13 years of age. Government quarters, when available, at rental of up to 10 per cent of basic salary (maximum £150 per annum).

Apply in writing to the Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, giving briefly age, qualifications and experience. Mention the reference number CDE 197/194/01.

UNIVERSITY OF GLASGOW

LECTURESHIP IN AGRICULTURAL BOTANY

Applications are invited for a Lectureship in Agricultural Botany. Salary scale £600 to £1,100 Initial salary according to experience and qualifications. F.S.S.U. and family allowance benefits.

Applications (eight copies), should be lodged not later than March 31, 1954, with the undersigned, from whom further particulars may be obtained.

RBT. T. HUTCHESON,

Secretary of University Court

BRITISH COTTON INDUSTRY RESEARCH ASSOCIATION

There are the following vacancies at the Shirley

Institute for research chemists who are honours graduates or graduates with higher degrees: 1. An Organic Chemist, for fundamental research on the chemistry of cellulose and its derivatives. 2. A Chemist, with a leaning towards physical and/or analytical chemistry, for fundamental research in cellulose chemistry. 3. A Physical Chemist, to study the degree of polymerization of macromolecular substances, with ultracentrifuge, etc. 4. A Chemist (or Physicist), with a knowledge of X-ray crystallography, for research on the structure of textile fibres. 5. A Chemist, with experience in infra-red spectroscopic techniques, for research on the structure of textile fibres and on the mechanism of dyeing. 6. A Chemist, for fundamental and technical research on the bleaching of textiles. 7. A Chemist, for fundamental and technical research on the chemical finishing of textiles. The minimum qualification for these posts is a second-class honours degree, and applications are invited from those doing National Service, from students taking degrees in 1954 and from people who expect to be available before the end of 1954. The starting salary for men and women who have just graduated will be £500 to £550 per annum, and up to £750 will be paid to those with research experience, a higher degree, or both. Some of the posts may be filled by more senior men, to whom starting salaries of up to £900 will be paid. All posts carry superannuation benefits under the Federated Superannuation System for Universities. Experience of textiles is not essential for any of these positions. 8. There is also a vacancy for a man to carry out investigations in textile finishing, the work being primarily concerned with increasing productivity in this section of the industry. Applicants should have a first- or second-class honours science degree and postgraduate experience, preferably of textile bleaching, dyeing and finishing processes. Starting salary for this post will be up to £900 per annum, and the post qualifies for participation in the Federated Superannuation System for Universities.

Application for all these posts, giving full particulars of qualifications and career, should be sent to Dr. F. C. Toy, Director of Research, Shirley Institute, Didsbury, Manchester, 20.

COMMONWEALTH OF AUSTRALIA

DEPARTMENT OF SUPPLY
HIGH SPEED AERODYNAMICS
LABORATORY

SALISBURY, SOUTH AUSTRALIA

Applications are invited for the position of Principal Scientific Officer (Supersonic Theory) with a salary range of £A.1,688 minimum to £A.1,874 maximum with the above Establishment. Duties: To initiate and be responsible for research, especially of a mathematical nature, in supersonic and transonic flow; and to exercise supervision over the work of other scientific staff and of a small computing "pool". Qualifications: Degree of high standard in mathematics, or equivalent qualifications, extensive experience of theoretical work in supersonic aerodynamics and ability to direct the work of others. Where permanent appointment is accepted, the successful candidate will be eligible to become a contributor to the Commonwealth Superannuation Scheme. Under specified conditions, first-class boat fare (if first-class berth available) of the appointee and his dependants (wife and dependent children) will be paid by the Commonwealth. There is difficulty in obtaining unfurnished accommodation in the Adelaide area, but the Department is prepared to help suitable applicants with this problem. While no definite assurances can be given, intending candidate should not let the housing problem deter them in making their initial application.

Applications to Senior Representative (A.P.10) Department of Supply, Australia House, The Strand, London, W.C.2, by April 5, 1954.

ST. THOMAS'S HOSPITAL

MEDICAL SCHOOL
(UNIVERSITY OF LONDON)

LONDON, S.E.1

Applications are invited for the post of Lecturer in the Sherrington School of Physiology. Appointment to start as soon as can be arranged and not later than October 1, 1954. Candidate must be medically qualified. Salary £800 to £1,100, according to qualifications and experience with superannuation and family allowance.

Applications, in triplicate, with the names of three referees, should be addressed to the Dean of the Medical School, and should be received not later than April 14, 1954.

SUGAR MANUFACTURERS' ASSOCIATION (OF JAMAICA), LTD.

Vacancies exist for three Senior Research Officers, to take charge of sugar cane research in the main ecological divisions of the sugar area. They are expected to study and know the conditions affecting sugar cane production in their respective divisions, with particular reference to soil/plant relationships (including nutrition, moisture and ripeness), soil management, chemical weed control, variety trials and disease and other surveys. Although much of the work is planned and co-ordinated centrally, officers should have initiative and the ability to formulate and develop their own complementary investigations. They will be posted to districts in accordance with their specialized knowledge and experience, and the nature of the dominant problems of districts. Applicants should preferably have had specialized postgraduate training in a branch of science applied to agriculture—e.g., plant physiology, soils, crop husbandry, or agricultural engineering. Appointments will be for a period of three years in the first instance. Selected candidates will be provided with free passages to Jamaica and required to assume duty not later than November 1, 1954. Leave with passages is granted after three-year service periods, and there is a contributory pension scheme. Salary will be in accordance with qualifications and experience.

Further particulars may be obtained from the Director of Research, Sugar Research Department, Mandeville, Jamaica, B.W.I., to whom applications, with full personal particulars, and three references, should be addressed to reach him as early as possible and before May 7, 1954.

RESEARCH FELLOWSHIPS IN GOVERNMENT SCIENTIFIC ESTABLISHMENTS

The Civil Service Commissioners invite applications for a number of Senior and Junior Research Fellowships, tenable for three years at Government Scientific Establishments, for research into subjects of importance to H.M. Government. There are no age limits, but candidates must have either a first- or second-class honours degree in an appropriate subject, and must be able to show evidence of a very high standard of ability in research. At least two years' postgraduate experience will be expected of candidates for Junior Fellowships, and at least three years' of candidates for Senior Fellowships. Remuneration will be according to individual merit and experience, at rates between £800 and £1,000 for Senior Fellowships, and between £500 and £700 for Junior Fellowships. F.S.S.U. scheme applies. The field of research in which Fellowships may be awarded if candidates of the requisite high quality present themselves cover a very wide range, and Fellowships may be tenable at any of a considerable number of scientific establishments.

Further information and application forms from Civil Service Commissioners, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1., quoting S.4300/54. Application forms to be returned by April 30, 1954.

UNIVERSITY OF NATAL SOUTH AFRICA

Applications from suitably qualified persons are invited for the following posts in the Department of Physics at the University: (a) Senior Lecturer at Pietermaritzburg, salary scale £1,050 by £50 to £1,400 per annum. (b) Two Lecturers, one at Pietermaritzburg and one at Durban, salary scale £800 by £50 to £1,050 per annum. Cost-of-living allowances at the rate of £234 per annum is payable in the case of married officers.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1. The closing date for the receipt of applications, in South Africa and London, is April 7, 1954.

THE LONDON HOSPITAL, WHITECHAPEL, E.1., has vacancy for Research Assistant in the Department of Neurology and Psychiatry. The major part of the work will be concerned with the development of E.E.G. equipment and techniques, including the taking of corticograms during neurosurgical operations. Applicants will require a good knowledge of electronic engineering and of the electro-physiology of the nervous system. Salary dependent on qualifications and experience.—Applications, giving names of two referees, should be received by the Secretary before March 27, 1954.

MONMOUTHSHIRE EDUCATION COMMITTEE

TECHNICAL COLLEGE OF MONMOUTHSHIRE, CRUMLIN

A Laboratory Technician, to take up duties on May 1, 1954, or as soon as possible after that date, is required at the above College. Candidates must have had experience as a Laboratory Assistant or Steward, and should have a good practical knowledge of one or more of the following crafts, viz.: scientific glass-blowing; carpentry; photographic processing; instrument or apparatus repair; or preparation of metallurgical specimens. Candidates should hold an appropriate ordinary national certificate or City of Guilds certificate. Salary £400 by £20 by £15 by £15 to £450 per annum.

Forms of application obtainable from the undersigned, to be returned not later than March 31, 1954.

C. B. GITTINS,
Director of Education.

County Hall,
Newport, Mon.

CITY OF CARDIFF EDUCATION COMMITTEE

COLLEGE OF TECHNOLOGY AND COMMERCE

Principal: Dr. A. Harvey

Applications are invited for the post of Assistant Lecturer, Grade "B," in the Department of Applied Physics and Electrical Engineering. Candidates should have a good honours degree in physics or electrical engineering. Some research, industrial or teaching experience is essential. The present salary scale for an Assistant Lecturer, Grade "B," is £490 by £25 to £765 per annum, plus appropriate allowances for training and degree. Applicants with suitable professional or industrial experience (over the age of 21) may be started higher up the scale at the rate of one increment of £18 for each year of such experience.

Forms of application, together with further particulars, may be obtained from the undersigned, to whom they should be returned as soon as possible.

ROBERT E. PRESSWOOD,
Director of Education.

City Hall,
Cardiff.

NORTHERN REGIONAL HOSPITAL BOARD (SCOTLAND)

Applications are invited from science graduates for a post of non-medical Biochemist in the Board's Laboratory Service. The main duties are at Craig Dunan Hospital, Inverness, with opportunity for biochemical investigations into mental illness. The post is in the basic grade, and the salary scale for candidates who have completed the probationary period is £385 by £30 to £765 per annum.

Further particulars and application forms are obtainable from the undersigned, with whom applications should be lodged by March 31, 1954.

A. M. FRASER, M.D.,
Secretary and Administrative
Medical Officer.

Office of the Northern Regional Hospital Board,
Raigmore, Inverness.

MINISTRY OF SUPPLY, R.A.R. ROCKET

Propulsion Department, Westcott, Bucks, requires: Scientific Officers (Ref. A.59/54A). (1) Mechanical Engineer, for work on liquid motors in project group. (2) Physicist or Physical Chemist, with mathematical skill, for internal ballistics section. (3) Physicist or Mathematician, for fundamental work on nozzle design and related problems in gas dynamics (heat transfer) section.

Qualifications, first- or second-class honours degree, or equivalent, in appropriate subject. Salaries within range £417 to £781. F.S.S.U. benefits may be available. Experimental Officer Class (Ref. A.60/54A). (1) Physicist or Engineer, for work on solid motors in development and project sections. Design experience useful. (2) Engineer, for experimental and theoretical work on development of components for liquid propellant rocket motors. Qualifications, higher school certificate (science), or equivalent, though further training in physics or engineering to H.N.C. or degree standard may be an advantage. Salaries within range, Experimental Officer (minimum age 26) £549 to £799, or Assistant Experimental Officer £254 (age 18) to £576. All posts unestablished. Women's rates somewhat less.—Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting appropriate reference. Closing date April 3, 1954.

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF ENGINEERING PRODUCTION

(1) Lectureship (Grade II) in Applied Statistics to date from July 1, 1954. Scale salary £530 to £1,100. Candidates should give details of academic qualifications and industrial experience, which should preferably be in production study or operational research field. (2) Tube Investments Research Fellowship, to date from June 1, 1954, or as soon as possible thereafter. Candidates should give details of their career and of their academic qualifications, and must also state the particular lines of research which they are desirous of pursuing within the field of engineering production and industrial management. The Fellowship is normally awarded for two to three years, subject to review each year, and carries a salary of £1,000 to £1,500 per annum, according to qualifications.

Applications (in triplicate) for the two appointments should reach the Registrar, The University, Edgbaston, Birmingham, 15, by April 30, 1954.

C. G. BURTON,
Secretary

The University,
Birmingham, 3.

UNIVERSITY OF BELFAST

The Senate of the Queen's University of Belfast invite applications for a Lectureship in Biochemistry from October 1, 1954. Salary range £550 by £50 to £850, and on certain conditions being fulfilled to £1,150, plus contributory pension rights under the F.S.S.U. Initial placing on the scale £550 to £850 is dependent on experience and qualifications. Applications should be received by April 30, 1954.

Further particulars may be obtained from G. R. Cowie, M.A., LL.B., Secretary.

ATOMIC ENERGY RESEARCH ESTABLISHMENT

Harwell, Berkshire, requires a Scientific Officer or Senior Scientific Officer for development work on carbon for nuclear reactors, involving structural studies of porous solids. Candidates should hold a first- or second-class honours degree, or equivalent qualification, in physics, chemistry or metallurgy. Some experience with carbon or in the ceramic field would be valuable, but is not essential. Salary according to qualifications and experience within the scales: Scientific Officer, £420 to £780; Senior Scientific Officer, £575 to £1,030.—Applications, quoting 2/103/70, giving full personal details, to the Establishment Officer, A.E.R.E., within two weeks.

MINISTRY OF SUPPLY RESEARCH AND DEVELOPMENT ESTABLISHMENTS

require Physicists with sound basic training, prepared to apply their knowledge to problems from many fields, including aerodynamics and aircraft structures, aircraft instruments, armaments, electronic circuits, radio and radar. Duties mainly experimental; may include trials work. Posts graded, according to qualifications and experience, in Scientific Officer class (requiring first- or second-class honours degree, or equivalent) or Experimental Officer class (requiring higher school certificate (science), or equivalent; pass degree may be an advantage). Salaries within ranges, Scientific Officer, £417 to £781; Experimental Officer (minimum age 26), £549 to £799; Assistant Experimental Officer, £254 (age 18) to £576. Women somewhat less. Appointments unestablished. F.S.S.U. benefits may be available for Scientific Officer class.—Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.1/54A. Closing date April 14, 1954.

NATIONAL COAL BOARD INVITE APPLICATIONS

for a supernumerary appointment as Scientist in the Field Investigation Group of their Scientific Department. Applicants should have a first- or good second-class honours degree (or equivalent) in physics, engineering, mathematics or statistics, and should, in addition, have several years' industrial or laboratory research experience. Experience in operational research would be an advantage. The successful candidate will be based in London, but will be required to lead a team carrying out field work at collieries. Appointment will be in the grade of Scientist either Grade II (£645 by £30 to £1,095 scale) or Grade III (£445 by £25 to £845 scale), salary being dependent on qualifications and experience. London location allowance is payable in addition.—Write, giving full particulars (in chronological order) of age, education, qualifications and experience (with dates), to National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, marking envelope TT/750. Original testimonials should not be forwarded. Closing date April 3, 1954.

H.M. COLONIAL SERVICE KENYA

Vacancies exist for (1) a Factory Inspector and (2) a Factory Inspector (Engineering) in the Labour Department of Kenya. For (1) candidates should possess a University degree in engineering or comparable professional qualifications (e.g., A.M.I.Mech.E.) and must have had experience of factory inspection or of a safety officer's work in a large industrial concern. Candidates lacking professional qualifications may however be considered if they offer exceptionally wide works or other special practical experience. For (2) a University degree or comparable technical qualification and a first-class Ministry of Transport Certificate (Steam) are required, but candidates who appear to be exceptionally well fitted by reason of extensive practical experience in the inspection of steam boilers and other pressure vessels, will be considered. Duties are similar to those carried out under United Kingdom factory laws. Appointments permanent and pensionable subject to probationary period. Salary scale £550 to £1,320, with initial salary dependent upon qualifications and experience. A non-pensionable cost-of-living allowance of 35 per cent of salary (maximum £350) also payable. Outfit allowance. Free passages for officer and family up to cost of three adult passages in all. Government quarters provided or allowance in lieu. Tour of service 40 to 48 months. Generous home leave. Free medical attention. Income tax at low local rates.

Further particulars and application form obtainable from the Director of Recruitment (Colonial Service), Colonial Office, Great Smith Street, London, S.W.1, quoting reference CDE 132/7/01/C1. Closing date for receipt of initial enquiries April 3, 1954.

COMMONWEALTH OF AUSTRALIA

DEPARTMENT OF SUPPLY AERONAUTICAL RESEARCH LABORATORIES

FISHERMEN'S BEND, VICTORIA EXPERIMENTAL OFFICER, GRADE 3 (Permanent position)

Salary £A1,154 to £A1,262 per annum. Duties: To carry out wind tunnel investigations related to the development of new aircraft and missile types. Qualifications: Degree or diploma in engineering, or equivalent qualifications. Several years' experience in wind tunnel investigations related to aircraft or missile development. Experience on rotary wing aircraft design also desirable. Where permanent appointment is offered successful applicants will be eligible to become contributors to the Commonwealth Superannuation Scheme. Under specified conditions first-class boat fare (if first-class berth available) of the appointee and his dependants (wife and dependent children) will be paid by the Commonwealth.

Application forms obtainable from Senior Representative (AP11), Department of Supply, Australia House, The Strand, London, W.C.2, with whom applications close by April 5, 1954.

MATHEMATICIAN REQUIRED BY MINISTRY OF Supply Guided Weapons Establishment, Aberporth, South Wales, to undertake responsibility for film reading and computation section, including interpretation of records, and investigation of new and modified analysis techniques. Qualifications: minimum of higher school certificate (science), or equivalent. Experience in computing section and some knowledge of instrumentation equipment and techniques desirable. Salary within range, Experimental Officer (minimum age 26) £649 to £799. Women somewhat less. Appointment unestablished. Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A58/54A. Closing date April 3, 1954.

BRITISH ELECTRICITY AUTHORITY. RE-placement of Scientific and Industrial Research, Forest Products Research Laboratory, Princes Risborough, Bucks, in the grade of Scientific Officer (unestablished), for investigations on timber strength, wood sawing and machining. First- or second-class honours engineering degree (civil or mechanical), training in the work when in post, knowledge of timber technology not essential. Minimum age 21. Inclusive annual remuneration for a 45½-hour week: £430 to £904 (men), £430 to £696 (women). Prospect of permanent pensionable post for candidates under 28—Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. C 99/53A. Closing date April 3, 1954.

PUBLIC SERVICE OF SOUTH AUSTRALIA

Applications will be received by the Public Service Commissioner, 31 Flinders Street, Adelaide, for the undermentioned positions until and including Friday, April 30, 1954. Applicants resident in England should forward their applications through the Secretary, Agent General for South Australia, who will also be available to answer any inquiries. Applicants should state full names, address, date of birth, marital status, academic qualifications, practical experience, and particulars of war service (if any). Copies of testimonials should be submitted with the application. Salaries quoted are actual and include cost-of-living adjustments to date.

Agricultural College Department—Senior Lecturer in Animal Husbandry. Salary Range: £A1,242 to £A1,347 or £A1,312 to £A1,417 per annum, according to qualifications and experience of appointee. Qualifications: A degree in science, veterinary science or agriculture, with some training in physiology and postgraduate experience. The successful applicant will be required to administer all phases of animal husbandry at the College, including the direction of policy in the various livestock branches and lecturing both to diploma and university students in selected phases of animal husbandry. The appointee will be expected to develop his own line of investigation. Considerable field and laboratory facilities are available. A house will be available for a married man at a rental to be fixed. **Museum Department—Entomologist.** Salary Range: £A1,117 to £A1,207 per annum. Qualifications: Applicants should have experience in the curating of insect collections (the South Australian Museum collection is unusually large, comprising upwards of two million specimens), and the ability to carry out entomological taxonomic research. Preference will be given to an applicant with a B.Sc. degree.

UNIVERSITY OF ST. ANDREWS

The University Court of the University of St. Andrews invites applications for appointment to the Chair of Chemistry in University College, Dundee. Candidates will be required to have special qualifications in inorganic or physical chemistry. The salary attached to this appointment is £1,900 per annum, together with F.S.S.U. benefits. The University operates a scheme of family allowances and a grant towards expenses of removal may be made. Candidates will be expected to take up duty, if possible, by about the beginning of September, 1954.

Further particulars may be obtained from the undersigned, with whom six copies of the application, together with the names of three referees, should be submitted not later than April 30, 1954.

DAVID J. B. RITCHIE,

Secretary of the University.

College Gate,
St. Andrews.

FACULTY OF MATHEMATICS

UNIVERSITY OF CAMBRIDGE

The Appointments Committee of the Faculty of Mathematics give notice that they intend to appoint from October 1, 1954, one or more University Lecturers and one or more University Assistant Lecturers. The appointments will be subject to the Statutes and Ordinances of the University. The stipend of a University Lecturer rises from £750 per annum to £1,250 per annum by annual increments of £50. The initial stipend of a University Assistant Lecturer is £600 per annum. Family allowances are payable.

Candidates should send their applications, with the names of two referees, to the Secretary of the Faculty of Mathematics, The Arts School, Bene't Street, Cambridge, so as to reach him by April 20, 1954.

ATOMIC ENERGY RESEARCH ESTABLISHMENT, Harwell, Berkshire, requires Experimental or Assistant Experimental Officers, for development work on carbon for nuclear reactors. One post involves high temperature work and the use of semi-technical scale equipment, and would suit candidate with engineering interests, particularly electrical. A second post is concerned mainly with laboratory examination and offers scope for a young physicist. Minimum qualification higher school certificate (science), or equivalent, but a degree in appropriate subjects would be advantageous. Minimum age 26 for Experimental Officer, 18 for Assistant Experimental Officer. Salary, according to qualifications and experience, within the scales: Experimental Officer, £650 to £800; Assistant Experimental Officer, £264 (at 18) to £580.—Applications, quoting 2/103/71, and giving full personal details, to the Establishment Officer, A.E.R.E., within two weeks.

McMASTER UNIVERSITY DEPARTMENT OF PHYSICS GRADUATE ASSISTANTSHIPS

Applications are invited for part-time teaching and research assistantships in the Department of Physics, McMaster University, from persons qualified to register in courses leading to the M.Sc. and Ph.D. degrees. Assistantships normally carry a yearly stipend of \$1,600 to \$1,850. Assistants are required to devote 10 to 12 hours per week during the academic season (October to April inclusive) and are able to devote full-time their research during the summer. Research is progress in the following fields: Theory; Molecular Spectra, F. R. Britton; Atomic Mass Determinations, H. E. Duckworth; Cosmic Rays, F. Gulber; Beta and Gamma Spectroscopy, M. V. Johns; Microwave Diffraction, A. B. McLean; Theoretical Nuclear Physics, M. A. Preston; Fusion Yields and Isotopic Abundances, H. G. Thode.

Interested persons should write to Dr. H. E. Duckworth, Department of Physics, Hamilton College, McMaster University, Hamilton, Ontario, Canada.

THE BRITISH RAYON RESEARCH ASSOCIATION

A number of Physicists are required to work on textile problems. Candidates should possess a good honours degree with some experience or training in research, not necessarily in textile research. Salaries will be in accordance with age and experience, and superannuation will be payable under F.S.S.U.—Applications to the Secretary, British Rayon Research Association, Barton Dock Road, Urmoston, near Manchester.

TECHNICIAN (PATHOLOGICAL) Required, for work in the new University Surgical Research Laboratories at the Queen Elizabeth Hospital, Birmingham. Candidates must have experience of histological methods, and the mounting of specimens, and a knowledge of any other skill, such as photography or metal work would be useful. Salary on University Scale (Grade C), according to age and experience.—Applications should be sent to the Professor of Surgery, Queen Elizabeth Hospital, Birmingham, 15, not later than March 31, 1954. Names of two referees to be given.

FARNBOROUGH, HANTS, ROYAL Aircraft Establishment Technical College (selective, day) requires Lecturer in Aircraft Structures, to teach subject to final B.Sc. and H.N.C. standard. Facilities for research may be available. Qualifications: good university degree, or equivalent, with considerable teaching and industrial or research experience. Salary on Burnham Technical scale, £900 by £25 to £1,000, plus £40 special addition and subject to Teachers' Superannuation Act. Housing accommodation to rent may be available to married man—Details and forms from Principal, to whom completed forms must be returned within fourteen days of this notice.

MATHEMATICIANS REQUIRED BY MINISTRY OF Supply Research and Development Establishments, mainly in Southern England. Wide scope of work, including research into aerodynamics and aircraft structures, high speed electronic computers, radio and radar, including aerial design and radiation problems, engineering problems, and trials work requiring good practical outlook. Appointments, according to qualifications and experience, as Scientific Officer (first or second-class honours degree in mathematics) £417 to £781; Assistant Experimental Officer (higher school certificate (science), or equivalent pass degree, including mathematics, may be at advantage), £264 (age 18) to £576; Experimental Officer (H.S.C., etc., but minimum age 26, with suitable experience), £649 to £799. Women somewhat less. Appointments unestablished F.S.S.U. benefits may be available for Scientific Officer class—Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London S.W.1, quoting A.2/54/A. Closing date April 14, 1954.

BRITISH ELECTRICITY AUTHORITY, RE-search Laboratories, Leatherhead, require a Junior Engineer for testing, development and research work in the laboratories and in the field, in connection with the generation of electricity. Candidates should have a H.N.C., or equivalent, qualification in electrical or need actual engineering or in physics. Salary N.I.L. Grade 6, £390 to £696.—Forms from D. Moff, Director of Establishments, British Electricity Authority, Winsley Street, London, W.1, to be returned by March 29, 1954. Quote reference N/461.

MANSFIELD OIL-GAS PLANT FOR LABORATORIES' GAS SUPPLY

• *Reliable* • *Simple to Operate* • *Safe*

Provides a gas supply at a constant calorific value of 1,350 B.T.U.'s per cu. ft. produced from Light Diesel Oil, Gas Oil, Paraffin, or other suitable oils available at low cost.

Enables the efficient use of most gas burning appliances available for towns' coal gas supplies in any part of the world. Ideal for glass blowing and gives perfect oxidising or reducing flames with ordinary burners.

For full particulars send details of estimated number of burners to be used.

POLARITAN REAGENTS

for polarographic analysis

Since the original introduction by Hopkin & Williams of POLARITAN REAGENTS in 1951, the list of reagents has been added to from time to time and the full range of reagents now available is given below:—

AMMONIA SOLUTION S.G. 0.88
AMMONIUM CHLORIDE
BARIUM CHLORIDE
CITRIC ACID
HYDROCHLORIC ACID
NITRIC ACID
POTASSIUM CHLORIDE
POTASSIUM HYDROXIDE
POTASSIUM THIOCYANATE
SULPHURIC ACID
TARTARIC ACID
GELATINE
LITHIUM HYDROXIDE
SODIUM SULPHITE

POLARITAN REAGENTS are supplied only by Hopkin & Williams Ltd. and the standards and methods of test have been formulated in collaboration with Tinsley (Industrial Instruments) Ltd.

A copy of the booklet "POLARITAN Standards for Polarographic Reagents", will be sent free, on request.

Gallenkamp

Laboratory Stirrer

£5.5.0
each

A utility laboratory stirrer with a small shaded-pole motor rated at 130 gm. cm. torque. The motor has no brushes to wear out, and complete absence of sparking makes it safe for use with inflammable materials. This motor runs at about 1,000 r.p.m. irrespective of load within wide limits, including running without load. An advantage is that the motor can be slowed by an overload without damage. The stirrer can be used without a rheostat unless speed variation is required. A rod, 1/4 in. diameter, is attached for mounting the motor on a retort stand, etc., and a switch is incorporated in the bracket casting.

Please apply for publication No. 530.

TWO SHILLINGS

THE *Newton*

LONG WORKING DISTANCE ATTACHMENT

... provides a working distance of 12.8 mm. between object glass and specimen when fitted to a standard microscope in conjunction with a conventional 4 or 8 mm. objective.

A further important feature is that the use of this attachment eliminates image reversal and thus further facilitates examination and manipulation of specimens.

High vacuum equipment

As high vacuum technique becomes more widely used in industrial processes, research work employing high vacuum equipment assumes an importance even greater than before. Metronick has always occupied a leading position in the research and development of apparatus dependent in some degree on high vacuum technique, e.g. X-ray apparatus, electron microscopes, vacuum coating plant, linear accelerators, cyclotrons, vacuum furnaces, etc. Complete vacuum equipments for the laboratory and the factory, as well as individual items such as vacuum pumps, valves, gauges, etc., are made by:

Taking the 'Frowns' from HIGH VACUUM PLUMBING

Nothing can be simpler than screwing down a metal ring by hand, and that is how easy becomes the complicated business of 'plumbing' high vacuum systems when 'SPEEDIVAC' vacuum unions are specified. Simple design and precision vacuum engineering eliminate long-standing problems—just a few turns of the wrist and you have a permanent, rigid, leak-proof connection—and it's just as simple to take down when necessary.

OSCILLOSCOPE FOR TELEVISION

Designed for maintenance of transmitter and studio equipment...

The value of the Type 524-D Oscilloscope to television networks, stations, and television development laboratories is confirmed by their enthusiastic acceptance. By June, 1953, over 300 of these specialized oscilloscopes had been placed in use. The following description tells why.

Variable delayed sweeps at the frame rate let you examine any portion of the television picture... from complete frames to small portions of individual lines. Any one of the picture lines may be located and observed in minute detail. A touch on Field Shift button provides a quick switch to the corresponding line or lines in the opposite field. Sweep magnifier expands the image 3x or 10x for detailed examination of synchronizing pulses. Internal markers are available to check timing accuracy. All other features meet Tektronix standards for laboratory-type oscilloscopes.

Type 524-D Oscilloscope

The *NEW* Muirhead-Wigan decade oscillator

TYPE D-650-A

THIS precision laboratory oscillator, which covers a range of 1 to 111,100c/s with an overall frequency accuracy of $\pm 0.2\%$ or $\pm 0.5\text{c/s}$, employs the decade tuning system, by means of which the frequency can be set quickly and accurately on four decade dials and a range switch. This system of tuning ensures the highest possible frequency accuracy and stability. It also enables a given frequency setting to be repeated exactly, and permits the addition or subtraction of a fixed number of cycles per second, thus giving an incremental accuracy of an extremely high order. No other type of oscillator possesses all these advantages.

FEATURES

Frequency range: 1-11,110c/s and 10-111,100c/s.

Frequency accuracy: $\pm 0.2\%$ or $\pm 0.5\text{c/s}$.

Hourly frequency stability: $\pm 0.02\%$ over most of range.

Maximum output:

2W into 8000 ohms above 20c/s.

50mW into 8000 ohms below 20c/s.

Harmonic content: 1% at 1W output.

Hum level: -80db relative to maximum output at 1000c/s.

Power supply: 200-250V, 50c/s; 90W. or 95-125V, 60c/s; 90W.

Dimensions: $17\frac{1}{2}$ in. wide x $10\frac{1}{2}$ in. high x 13 in. deep.
(43.8 cm x 26.7 cm x 33 cm).

Weight: 83 lb. (38 kg).

A NEW PERIODIC TABLE OF THE ELEMENTS

based on the

STRUCTURE OF THE ATOM

by

S. I. TOMKEIEFF, D.S.C., F.R.S.E., F.G.S.

Size: 13½" x 12"

Illustrated in colour and black and white, and with a cut-out chart suitable for mounting as a cover

10s net

A feature of this book is the comprehensive Table of Elements. These are arranged in order of atomic numbers and all their fundamental properties are listed, including electronic structure, number of active electron shells, and type of atom. This is the most complete and up-to-date table yet published and will serve as a valuable reference for all chemists and physicists. The text contains a full explanation of the theory of atomic structure and its relation to the periodic system, and the 'build-up' of the system is shown by means of a chart. A novel formula relating the number of elements in a given period with the number of electron shells in the atoms belonging to this period is also given (see 'Nature,' Vol. 167, p. 954, 1951).

(Readers may recall Dr. Tomkeieff's contribution on this subject published in Nature on 27 February, 1954, p. 393 et seq.)

37 ESSEX STREET, LONDON, W.C.2

PRECISION

INSTRUMENTS

Refractometers for Industry and Research

Our well-known standard Abbe type refractometer has a refractive index scale on glass and is read by transmitted light, thus leading to greater convenience in taking measurements and a higher degree of accuracy.

The instrument as illustrated is supplied with degree scale arc and micrometer screw reading directly to 10 seconds, corresponding to a refractive index accuracy within 0.00005. Conversion tables for use with sodium light are supplied.

DELIVERY FROM STOCK

Full particulars sent on application.

We shall be pleased to demonstrate these instruments and give any advice within our power, if you will call at our Works.

ACADEMIC FREEDOM: ITS WORLD-WIDE SIGNIFICANCE

AT the seventh Quinquennial Congress of Universities of the British Commonwealth at Cambridge last July, which opened with a discussion on the relations which should exist between governments and universities, and at the International Congress on Science and Freedom held at Hamburg later the same month, warm tributes were paid to the University Grants Committee as a model for the distribution of government subsidies to universities. However, Dr. H. W. Dodds, president of Princeton University, indicated that the device is unsuitable for the universities of the United States, where its introduction would almost certainly expose the universities to undesirable pressures which are not experienced in Great Britain. He is of opinion that political, psychological and constitutional reasons make it unlikely that grants could be made unconditionally in the United States.

On the other hand, Dr. E. G. Malherbe, principal and vice-chancellor of the University of Natal, warmly advocated the application of this device to the finance of the South African universities, and it appears from the report of the Holloway Commission, tabled in Cape Town last summer, that this is likely to be done. The Commission was appointed in August 1951 as a result of widespread dissatisfaction with existing university salaries and with the present rigid and inelastic State subsidization, which had, in fact, broken down. The Commission holds that to enable the universities to fulfil their functions they require not only more money, with safeguards to the State against unrestricted financial obligations, but also greater freedom. The idea of attaching strings to the subsidies by regulations for State control was rejected by the Commission, which suggested an independent University Grants Committee, mainly to administer specially voted funds for research, but also to inspect the work of the universities, to watch over their development and to advise the Minister of Education on their financial needs.

These proposals, on which the South African Government has yet to announce its decisions, differ in some respects, which may prove important, from the arrangements for the University Grants Committee in Great Britain, and the significance of these differences may perhaps be seen in remarks which Prof. W. H. Hutt, of Cape Town, made at the Universities Congress. Prof. Hutt pointed out that in order to defend their independence when they are dependent on Government finance, universities have to weigh what they do and say in the light of their responsibilities, and they have to work together. This is not easy in South Africa, where the penetration of politics into university affairs now prevents Afrikaans and English universities from co-operating fully. Indeed, it is doubtful whether the conditions in which a University Grants Committee could function exist there, any more than in the United States.

Although this specific issue was not discussed at the International Congress on Science and Freedom

held at Hamburg, that Congress threw some light on the general principles which should govern the relations between governments and universities. To academic freedom, as to science, the most obvious danger comes with the enforcement of some extra-scientific or extra-academic canon of orthodoxy. Scientific advance and the functioning of the university are alike hindered when governments intervene indiscreetly and usurp or abolish the self-direction of university or scientist. The danger can arise not merely ideologically but also out of the utilitarian demands of the government making the grants. In Great Britain, apart from the discontinuance of the ear-marked grant, the Government has shown a most marked respect for university autonomy, as may be seen, for example, in the Treasury's latest reply to the recommendation of the Committee of Public Accounts that the books and accounts of the universities relating to expenditure of non-recurrent grants should be open to inspection by the Comptroller and Auditor General. Elsewhere, however, there is perhaps more danger that, in the legitimate initiation of projects in applied or fundamental research, governments may be less careful to avoid monopolizing them or allowing the objectives of their general policy to absorb too much of the available resources of the universities.

One of the essential conditions of scientific advance is that the scientist should have the freedom and resources to follow his own bent; and universities make their contribution to the advancement of learning, whether by teaching or research, under like conditions. When governments seek to order, instead of to foster, scientific or other creative activity, frustration sooner or later results. The first lesson a government has to learn in respect of the advancement of knowledge is to leave well alone, to see that the universities, the learned societies and scientific institutions and the individual scientists are not denied the necessary resources, and then to give them their head.

Prof. Ludwig Raiser, in an address at the Hamburg Congress on State support of universities and academic freedom, attached little significance to any audit by the State of the accounts of such an institution as the University Grants Committee, on the ground that the academic body itself would be no less concerned than the State to ensure the soundness of its accounts. He recognized, however, the importance of any such body as the University Grants Committee possessing the status enabling it to deal with the State on relatively equal terms, and to undertake the distribution of its funds expertly and impartially in a way that cannot be affected by any external pressure or sectional interests. Given such conditions, Prof. Raiser believes that financial support from the State will not prejudice academic freedom.

Such conditions, he recognized, are not universal even in the democratic countries. That they do not exist in the United States, for example, is one reason why the device of a University Grants Committee is regarded as unsuitable for introduction there. It would appear, moreover, that even if there were

achieved the general public understanding of the essential character of the relations between the universities and the State which it is intended to serve, application of the device in the United States would still be unsuitable. Nevertheless, in the United States as elsewhere, the public has to be convinced of the decisive importance of academic freedom both for the national welfare and for the advancement of science; otherwise the universities, scientific institutions, learned societies and professional associations are likely to be handicapped seriously in their work by the forces and passions released under loyalty-security investigations.

Dr. J. D. Millett, president of Miami University, described the problem as that of giving reality to the ideals of a free society, and said that the crucial issue of our time is the discovery and invention of satisfactory practices for enabling universities to do their work while maintaining their vital characteristics as centres of unhampered intellectual endeavour. These practices will necessarily vary from one society to another; dangers acute in one community may be less serious in another, where other factors may present a much greater threat to academic autonomy. Moreover, even in the academic world, there is the danger to which Prof. Jean Thibaud, of the University of Lyons, directed attention, that the age-factor itself may militate against a sufficiently adventurous administration of funds for the advancement of learning. Seniority may avoid the danger of indoctrination to which the entrusting of authority to younger people is liable, but it may itself fail to be sufficiently adventurous or receptive to new ideas, and such reluctance is usually accentuated if the administrative body is a government organization.

The great dangers of centralization were thus amply emphasized at the Hamburg Congress, and there was universal agreement that no central authority should have the right to dictate or to restrict the objectives of academic inquiry. Even more welcome, however, is the evidence in the United States, in the Commonwealth of Australia, in the Union of South Africa and in Japan that attempts to interfere with academic freedom—of investigation or of teaching—are meeting with vigorous protest and opposition. Resistance to such interference can scarcely fail to be strengthened by the exposition of general principles at the Hamburg Congress and the evidence of uniformity of world opinion on the issues at stake.

As Prof. M. Polanyi pointed out, when the State establishes institutions for the cultivation of science, it recognizes a realm of independent ideas and independent men. It admits that the requirements of this realm may demand consideration on an equal footing with the political and material interests of the society it guards, and by implication the State accepts also the obligation to foster the advancement of this realm under the guidance of recognized academic leaders. Academic freedom, as a principle for the efficient organization of the advancement of science, implies the right of independent thought, and Polanyi rightly insisted that for its defence and re-establishment to-day in the face of a more penetrating and comprehensive critique of its

foundations, liberty must be formulated in more concrete terms.

The situation in the universities in South Africa, where the threat to academic independence is much sharper than in Australia, illustrates the point admirably. At present there are about 240 non-European students at the University of the Witwatersrand out of a total of about 4,000, and some 219 non-Europeans at the University of Cape Town; the 222 non-European students at the University of Natal receive tuition in separate buildings and never come in contact with Europeans. Apart from one or two small teacher training colleges, the only other institution of higher learning in South Africa open to its 9 million non-Europeans (out of a total population of 12 millions) is the University College of Fort Hare, and of the 17,500 students in South Africa, only about 1,160 are non-Europeans.

The recent Commission on Higher Education for Africans in Central Africa, where the disparity in numbers between European and non-European population is even more marked, observed that an institution of university rank is an essential possession of a community which has reached a certain stage of development and has a sufficient population and adequate resources; and that although the number of university-trained Africans now employed in the Rhodesias and Nyasaland is small, it would be wrong to conclude that the need for such Africans is limited. Nevertheless, hitherto in South Africa only the Universities of Cape Town and the Witwatersrand have conformed to the essential university tradition that no regard should be had to race, religion or class when selecting candidates for admission. It is not contrary to university practice, as the Carr-Saunders Commission points out, to reserve certain halls of residence or hostels for particular classes of student; but it would be repugnant to university tradition deliberately to place hostels so reserved at a greater distance than other hostels from the centre of the university. The segregation of particular classes in separate buildings for tuition, as in the University of Natal, is a manifest breach of tradition.

The stress which the Commission laid in its report on these matters may appropriately be recalled here. No test of religious or political belief was to be imposed as a condition of becoming a member of the staff or a student at the proposed University of Rhodesia, and the effective autonomy of the University and the independence of its multi-racial basis of any political or other external pressure were emphasized. In South Africa, however, not only has it now become apparent that the *apartheid* policy of the Government does not imply, as has primarily been contended, the gradual extension of higher educational facilities for all racial sections: it has also become clear that there is no intention of providing equal facilities for non-Europeans, and that the transfer of non-European education from the Minister of Education to the Minister of Native Affairs presages an attempt to carry the principle of discrimination and segregation from top to bottom of the field of education.

In this situation the attacks continually made since 1948 on the Universities of Cape Town and the Witwatersrand, where there is a policy of non-segregation, by members of the Government and others, have now begun seriously to threaten the autonomy of these Universities. During the last session of the Union Parliament, the Minister of Education announced that the Cabinet would consider the problem of university *apartheid* during the recess, and expressed the hope that the universities would co-operate in ending what he termed an intolerable position. While he disclaimed any intention of threatening the academic freedom of the universities, when pressed on the point in Parliament, he denied that this would prevent the Government intervening on the colour question, and in September last a Government newspaper stated that there was every reason to suppose that the Government was firmly determined to come to the next session with the necessary legislation if the universities were not prepared to take the necessary steps themselves. Furthermore, the Union Government has already, on December 18, 1953, proclaimed a Commission "To investigate and report on the practicability and financial implications of providing separate training facilities for non-Europeans at universities".

It appears to be improbable that the Union Government will secure the voluntary co-operation of the two Universities in question. The Council of the University of the Witwatersrand recently affirmed the existing policy of the University, and the acting principal of the University of Cape Town, Prof. W. R. James, after expressing the view that the evil results of allowing European and non-European students to attend the same classes were wholly imaginary, said that if *apartheid* was enforced by legislation the University would presumably obey; but that it would be most unwilling to lose a freedom enjoyed by nearly all the great universities of the world. The National Union of South African Students, the 11,000 members of which are drawn mostly from the English-speaking universities, has taken a strong stand in defence of non-segregation and university autonomy, and in conjunction with the Students' Representative Councils of both universities is doing what it can to combat Government interference.

On February 15 a statement protesting at the projected extension of racial segregation in the South African universities was issued by the Bishop of Johannesburg and twenty other signatories. Questioning the need for interfering with existing practice in the open Universities of Cape Town and the Witwatersrand, and denying that friction or internal tensions have arisen through the open system, the statement declares that a university must be free to attract the most able students in every racial group, to welcome independence of outlook and to promote the fruitful interaction of mind upon mind. The very existence of the two open universities, it argues, has enhanced South Africa's reputation overseas and given concrete expression to the desire for goodwill between Europeans and non-Europeans. To destroy the open system and replace it with complete, or even with internal, segregation would destroy one

of the last bastions of tolerance and enlightenment in South Africa and drive bitterness and despair into the heart and mind of the non-European.

An independent and informed observer may well reflect that, when all allowance is made for the natural irritation of a government at the opposition, perhaps not always tactfully expressed, of student bodies to its policy and proposals, the open universities of South Africa in their resistance to the imposition of *apartheid* from outside are fulfilling the same functions that the medieval universities, and especially the University of Paris, once exercised in Europe. Even when no restrictions are placed on the Press, on the platform or on the polling booth or ballot box, a body of educated men, such as a university faculty, have an essential function to play in a free society; nor can they continue to test, criticize and re-assess existing institutions and beliefs, approving or disapproving in the light of the evidence available, unless their independence matches that responsibility. In the democratic State of to-day, with so much tendency towards centralization, this function of criticism and discussion by independent groups and associations is vital to the preservation of freedom of utterance, of thought and of association, and for the prevention of the transition, by an insidious process of attrition, of a democratic into a totalitarian regime. No university can tolerate such interference as is now threatened in South Africa without losing its soul, and university teachers, officials and students will have the respect and support of their colleagues elsewhere in the Commonwealth if they show something of the turbulence of the old medieval universities when academic privileges and rights were invaded.

We are not considering here the general question of segregation or *apartheid* in South Africa. The rest of the Commonwealth may regret a decision in that sense, may think it mistaken, and may even have to pay a heavy price for it; but the decision is one for South Africa to take. What is no less true is that if segregation is to be adopted as a policy in the open universities, it must be on their own free decision, as a result of reasoned argument and the balancing of pros and cons, and not at the external dictation of Government or even Parliament. Once university autonomy is thus infringed, the value of the university as an independent centre of informed impartial criticism disappears.

Neither the Universities Congress nor the Congress on Science and Freedom can have left the Government of South Africa in any doubt as to the absence of sympathy for any such inroads into academic freedom as are threatened. A modern community, however, has such imperative need of independent centres of reflexion, criticism and judgment that it is not too much to hope that wiser counsels will yet prevail. As Lord Lindsay once emphasized, the universities and the churches have an essential part to play in preventing the disintegration of a community in the modern world. Their freedom and functions are not merely the remnants of a medieval tradition. The freedom of the modern university, Mr. R. M. Hutchins, formerly chancellor of the

University of Chicago, has rightly said, is based on the proposition that societies require centres of independent thought and criticism if they are even to survive, and the function cannot be exercised unless freedom is guaranteed. The independence of thought that proceeds in a true university is thus too important to be curbed, even if it leads on occasion to the expression of reasoned views which are unpopular with a government or with particular groups or sections of a community.

How valuable that function of reflexion, discussion and criticism, and of social and educational experiment could be in the African world to-day is apparent from such a book as Prof. S. H. Frankel's "The Economic Impact on Under-developed Societies"*. Bringing out the complexity of the human and social problems involved in technical change, Prof. Frankel insists on the urgent need for a continent-wide study of these questions in Africa. In problems of human relations there are no easy or final solutions, and for solutions which offer hope of avoiding disintegration to be accepted they must be based on inquiry and study, the integrity and impartiality of which command confidence. Once confidence in the ability of a university institution to undertake such studies impartially and objectively is undermined, the basis of co-operation is destroyed. The Union Government might well reflect that hasty interference with academic freedom may destroy both the foundations of social order and one of the last hopes of averting racial disaster in Africa.

* *The Economic Impact on Under-developed Societies*. By Prof. S. H. Frankel. Pp. viii+170. (Oxford: Basil Blackwell, 1953.) 15s.

RESEARCH IN SCHISTOSOMIASIS AND ITS VECTORS

MIYAIRI'S discovery of the life-cycle of the fluke *Schistosoma japonicum* in 1913 raised hopes that the diseases caused by it and its allies might be controllable through their intermediate snail-hosts. These hopes were strengthened by Prof. R. T. Leiper's classical work in Egypt in 1915 on *S. haematobium* and *S. mansoni*; but, unfortunately, this early promise has not been completely fulfilled, and schistosomiasis remains one of the more intractable of tropical diseases.

It was assumed that a knowledge of the habits and ecology of the vector snails, once their identity had been established, might reveal stages in the cycle where mechanical, chemical, or biological control would be practicable. This assumption is probably sound; but the difficulties that have arisen have been mainly in connexion with the essential first step, which is to establish the identities of the vectors. Despite the vast amount of work that has been done on gastropod shells (under the urge of paleontological necessity and nineteenth-century fashion), relatively little attention has been paid to the snails that inhabit the shells, and it has become abundantly clear that the conchologists' 'species' are not recognized by the parasites. It also seems likely that

the ability to acquire and transmit schistosome infection is not a constant character even of a true biological species, but may be influenced by other factors, some environmental and some associated with infra-specific categories both of host and parasite. The problems are essentially biological, and the attack on them requires the closest collaboration between workers in different fields—experimentalists, ecologists and, especially, malacological taxonomists.

Since the disease is widespread, it is appropriate that the World Health Organization should co-ordinate national efforts and, to this end, a preliminary conference was recently held in Paris to compare notes on the taxonomic position and to discuss future research. The meeting was mainly concerned with the disease in Africa, and, as a major Colonial power in that continent, Britain is intimately concerned; but, unfortunately, it possesses no zoological organization whose normal responsibilities cover the whole field and which has all the necessary facilities.

Much of the work clearly falls within the scope of the British Museum (Natural History), which is acutely aware of the importance to medicine and animal husbandry of a more intensive study of the taxonomy of helminths and their vectors. Modern taxonomy requires, for the recognition of natural species, as complete a knowledge as can be obtained of the full extent of variation of all populations that can be shown to be normally interbreeding. Furthermore, taxonomy requires this knowledge over the whole range of environmental conditions under which the animals can, and do, exist. The same knowledge would also go a long way towards supplying the basic needs of those seeking for methods of control, and consequently the Colonial Medical Research Committee and the Museum are considering together suitable methods of providing research facilities. Inevitably financial consideration will limit the scope of their efforts.

In the circumstances, it is worth while directing the attention of biologists to the research fellowships which are being offered by the Civil Service Commission. Two classes of fellowships are offered: senior awards, of the value of £800–£1,000 a year, and junior awards, of the value of £500–£700, and the usual universities superannuation scheme applies to both. There is no age limit, but three years of post-graduate experience in research will be required of candidates seeking senior awards and two years of similar experience for junior awards. Fellowships are tenable for three years at a Government research establishment, "for research into subjects of importance to H.M. Government"—terms of award broad enough to cover the whole field of scientific endeavour. No doubt consideration would be given to the biological aspects of schistosomiasis and its vectors if candidates of suitable qualifications come forward. The problem is of outstanding importance from the points of view of both human affairs and biology, and it is to be hoped that this opportunity of advancing knowledge will be seized without delay.

A PIONEER OF MICROBIOLOGICAL EXPERIMENT

Abraham Trembley of Geneva

Scientist and Philosopher, 1710–1784. By Dr. John R. Baker. Pp. xix+259. (London: Edward Arnold and Co., 1952.) 35s. net.

THE lives and achievements of eminent scientific men have been, in general, well explored. Thus the biography of science tends, more and more, to works on lesser figures. It is therefore refreshing to encounter a careful study of a neglected yet highly distinguished exponent of scientific method. Dr. J. R. Baker is well known both as a cytologist and as the historian of the cell theory, quite apart from his editorship of the *Quarterly Journal of Microscopical Science* and his philosophical writings on freedom in science. He is indeed peculiarly well equipped for investigating the life-work of Trembley, to which he has devoted much care and skill. This most readable book is not likely to be superseded.

Not only students of biological history but also many of those who love beautiful books for their own sake know Trembley's "Mémoires pour servir à l'histoire d'un genre de polypes d'eau douce, à bras en forme de cornes" (Leyden, 1744). It is famous both for its admirable plates, drawn and engraved by Trembley's friend, Pieter Lyonet (1707–89)—one of the most skilled micro-anatomists of all time—and for its exquisite vignettes of the gardens and house in Holland where Trembley lived and worked during his most productive years. His achievements are most attractively presented by Dr. Baker in their scientific and social backgrounds.

Trembley was essentially an experimental physiologist who studied a few organisms, but those intensively. Such naturalists were rare in the century dominated by Linnaeus (1707–78), who sought to survey ever larger and larger numbers of species, to arrange them and to find patterns common among them. Of the physiological and intensive type of naturalist three contemporaries stand out pre-eminently—Trembley, Lyonet and, above all, de Réaumur (1683–1757). The three were in such close association that Dr. Baker has often to consider them together. For Trembley he makes the following claims, which we set out, almost in Dr. Baker's own words, though a little qualified here and there.

(1) He was the first serious student of animal reproduction by budding, the first to prove experimentally that the process is asexual, and the first to discover that budding of new individuals occurs in animals other than hydra and notably in Polyzoa and Annelida.

(2) He was the first to show that certain animals can be artificially multiplied by division and the first to make a single individual by grafting two animals together. Dr. Baker's additional claim that Trembley was the first to make permanent grafts of animal tissue should perhaps be reconsidered with reference to Tagliacozzi (1546–99) and certain even earlier workers.

(3) He discovered that Protozoa multiply by division, and form colonies when the division is not quite complete; he was among the first to witness cell-division and certainly the first to see it in a single-celled alga.

(4) He described some of the salient physical characters of protoplasm, 101 years before Dujardin.

(5) He was the first to describe the anatomy of a polyzoon. The general recognition of the animal nature of Polyzoon and sessile coelenterates was largely due to him.

(6) Of techniques, he introduced that of vital dyeing. He also adopted an injection process in which the colouring matter was forced through the body cavities by the animal's own muscular movements, thus demonstrating that the tentacles were hollow, their cavities being continuous with the main coelenteron.

His best-known achievements are, of course, his intensive study of the structure, habits, life-history, and methods of reproduction of *Hydra* and his extraordinarily skilled experiments with several species of this creature. For all of them he used no more than the most elementary apparatus. His microscopes were single lenses of very short focal length, each carefully mounted in a metal disk and held by a metal rod divided into segments by a series of universal joints. Trembley, like his friends Lyonet and Réaumur, was above everything a reliable and resourceful observer. He had a temperamental objection to hypothesis. Excess of caution has its nemesis, and these great observers, unlike their less cautious contemporaries, Buffon (1707-88) and Bonnet (1720-93), failed to find successors or to found schools of thought. Trembley was far from a voluminous writer, and Dr. Baker's careful bibliography contains only twenty-eight items, which include his philosophical, educational and religious works, together with reprints, reviews and contributions to journals. Few great naturalists have written so little and that little so good. Dr. Baker's book has a model index. It contains, under the heading 'Trembley, Abraham', a convenient chronological epitome of his life. In general, the biographical details are interwoven with the scientific with unusual skill. The book is beautifully illustrated and produced and is not expensive, as the prices of such things rule nowadays.

CHARLES SINGH

USE AND THEORY OF MATHEMATICAL ANALYSIS

Differential Equations

By Robert C. Yates. Pp. vii+215. (London: McGraw-Hill Publishing Co., Ltd., 1952.) 32s.

Advanced Mathematics in Physics and Engineering
By Prof. Arthur Bronwell. Pp. xvi+475. (London: McGraw-Hill Publishing Co., Ltd., 1953.) 51s.

Complex Analysis

An Introduction to the Theory of Analytic Functions of One Complex Variable. By Prof. Lars V. Ahlfors. (International Series in Pure and Applied Mathematics.) Pp. xi+247. (London: McGraw-Hill Publishing Co., Ltd., 1953.) 42s. 6d.

IN "Differential Equations", by Mr. R. C. Yates, of the United States Military Academy, West Point, a first course in differential equations is presented, suitable for the student of physics or technology; it covers the explicit solution of elementary first- and second-order equations, and includes brief introductions to the formalities of solution in series, Legendre and Bessel functions, simple partial differential equations and Fourier analysis. The

numerical methods of Runge-Kutta and Picard are given a short chapter. The author is well aware that the mathematician may cavil at the omission of existence theorems, convergence of series, and other matters of logical importance; but he is thinking primarily of the user and is content to refer to more advanced texts for these refinements. For students in the Armed Services, the need to relate mathematical methods to service problems is over-riding; and here Mr. Yates serves his readers well, since in most instances a new topic is introduced by means of particular and concrete problems, and the number of exercises for the student is ample. Moreover, Chapters 4, 8, 11, 15 and 19 bear the title "Summary and Review Problems", and in these the student can find an epitome of the preceding work and a further collection of relevant exercises. Perhaps Chapter 13, on Legendre and Bessel equations, should have been placed after Chapters 16 and 17 on partial differential equations, since then the bald statement that these are "two of the most important differential equations that occur in mathematical physics and engineering design" could be made more readily acceptable to the novice; but this is a very small blemish on a pleasant and useful introduction to a subject of high technical importance.

Prof. Arthur Bronwell is professor of electrical engineering in the North-Western University, Evanston, Ill.; naturally, his interests are on the technical side, and his volume, "Advanced Mathematics in Physics and Engineering", could be used as a sequel to that of Mr. Yates. His task is, however, more difficult, since he wishes not only to expound mathematical methods, such as infinite series, differential equations, vector analysis, Fourier series, complex variable and Laplace transform, but also to use these in an account of dynamics, circuit theory, heat flow, hydrodynamics and electromagnetic theory. Five hundred pages is perhaps too short for so vast a design, yet the chapters on these physical applications, while compact, are not obscure, though in one or two places more stress on the physical bases would have been helpful. The purely mathematical chapters do not appear to have received so much care in their construction; there are many loose and casual statements, while in the earlier paragraphs of Chapter 2 (complex numbers) and Chapter 10 (vector analysis) it is extremely difficult—and the novice might well find it impossible—to determine what is definition and what is inference. The notion that the technician need not understand a method so long as he can use it is antiquated; the really powerful mathematical tools must be understood in order to be efficiently used. Prof. Bronwell's massive compendium shows the use of many of these tools, but for a full understanding the reader should supplement accounts here given by referring to some of the authoritative texts mentioned in the chapter bibliographies.

As befits a pupil of Ernst Lindelöf's, Prof. L. V. Ahlfors writes for the mathematician. In "Complex Analysis" his topic is classical, though he has been able to find room for some fairly recent additions, notably subharmonic functions and Perron's method for solving Dirichlet's problem. There are, however, novelties of exposition. The student is not hastily presented with Cauchy's theorem; in fact, this does not appear until p. 88, and then only for a rectangle and a circle, the general theorem coming twenty pages later. Very wisely, the way is prepared by a thorough study of simple topological notions, and

by considerable attention to elementary conformal mappings. Good in itself, this study prepares the reader for the two-fold aspect, topological and analytical, of Cauchy's theorem, where Artin's ideas make for comparative simplicity. In effect, Prof. Ahlfors outs the topology of the subject to the minimum and then gives that minimum with the utmost clarity and precision. The calculus of residues receives meagre treatment: it is off the main line, and Lindelöf's own beautiful monograph is easy to obtain. Elliptic functions are excluded, Prof. Ahlfors expressly referring the reader to Copeston's classical book on the complex variable. Space thus saved is given to two chapters, one on the recent work referred to above, and the other to the theory of multiply-valued functions, which is clear enough as an introduction but scarcely goes far enough to be either satisfying or provocative; twenty pages more here might have explored the main foundations of algebraic functions. In all, this is a clear, authoritative, up-to-date treatise, thoroughly suitable for the undergraduate beginning to specialize in function theory.

OCCURRENCE OF PETROLEUM IN THE EASTERN HEMISPHERE

The World's Oilfields

The Eastern Hemisphere. Editor: Prof. V. C. Illing. (The Science of Petroleum, Vol. 6, Part 1.) Pp. viii + 174. (London, New York and Toronto: Oxford University Press, 1953.) 52s. 6d. net.

LIKE the previous addenda to "The Science of Petroleum", this is a very fine book. Written by a selection of contributors, each vessel in a particular terrain, it deals with the subject as a whole and forms a work of reference limited only by the knowledge available at the time of writing. Therein, as is natural, may lie a few limitations. So far as petroleum at present is concerned, the "Eastern Hemisphere" is chiefly Europe and the Middle East. In the case of Europe, information that is, or has been, readily accessible (such as that regarding Germany, Poland and Roumania) is already fairly well known; what has not been accessible and was mostly unknown when volume 1 of "The Science of Petroleum" was published in 1938 (for example, developments in Austria and Hungary) includes the more important new fields largely developed subsequent to the outbreak of the Second World War and still behind the Iron Curtain. The result is that in these sections, where knowledge of production is sparse, the treatment seems rather heavily weighted on the side of general geology. This is so, to some extent, even with the important fields of the Middle East, on which however, by reason of their broader outlook, the articles by Lees are refreshing to read. Although oilfields are sub-surface affairs, it is natural that exploration, their discovery, delimitation, development and handling of production should be of the widest interest. One is consequently apt to miss the treatment in Vol. 1, wherein a single part of discussion of individual oilfields was in proportion to some five parts of the general aspects of production concerned with geophysics, siting, drilling, field-engineering and transportation.

The present volume is therefore of greatest importance to students and workers in the field of petroleum geology. The pattern of treatment in the

sub-sections is to follow a short introduction with details of the stratigraphy and tectonics of the area concerned. The oil-source rocks are then discussed separately. Good use is made throughout of effective tabulation, and maps and diagrams are excellent. The sections dealing with the Far East and Australasia, and with Africa, contain articles by fourteen separate authors. They vary in length; but the majority, though short, succeed in giving general outlines of the oil geology of the extensive but not very productive areas concerned. In this way, the implications of subsequently acquired information or discovery afterwards made can readily be fitted in.

Prof. Illing and his contributors are to be congratulated on producing a volume which will be of permanent value in the study of the occurrence of petroleum.

S. J. M. AULD

MARGINAL LAND IN BRITAIN

Marginal Land In Britain

By Prof. W. Ellison. Pp. 224 + 16 plates. (London: Geoffrey Bles, 1953.) 25s. net.

PUBLIC attention has been directed repeatedly in Great Britain to the possibilities of marginal land improvement during the past ten years or so, and the absence of any comprehensive book on the subject has meant a substantial gap in agricultural literature. This gap is now filled very adequately by Prof. W. Ellison's book. It cannot be easy to write a book which will be read with interest and profit by both the farmer, on one hand, and the scientist and administrator on the other. Prof. Ellison, we know, is an enthusiast for reclamation and rehabilitation of the land and farmsteads of British uplands; but unlike so many agricultural enthusiasts before him, he has been content to give an ungarnished factual account of the nature and extent of the problem, drawing on his own and other people's practical experience to show with facts and figures how production can be increased from this type of land, and at what cost. It is a great merit of the book that the agricultural problem of marginal land in the uplands is always kept in perspective, both in relation to its alternative use for forestry and water-gathering grounds, and to the needs of the lowland farmer upon whom the upland farmer so largely depends.

The book begins with a historical introduction and goes on to describe the findings of the various committees which have considered the problem in recent years. The different types of marginal land in Great Britain are defined and delineated on folding maps. There follow valuable sections on the methods of improvement appropriate to these different types and on the utilization of the resulting increase in production of crops and grass. The author's discussion of the extent to which, in the uplands, rehabilitation of the farm-houses, buildings, roads and services must accompany improvement to the land is based on actual surveys, which emphasize the high capital costs involved.

If there is an omission from this otherwise well-balanced book, it is perhaps the relatively slight reference to the personal factors in this problem—the labour force (family and hired); the landlord; and, most important, the abilities and shortcomings of the farmer himself.

THE AMATEUR SCIENTIST IN BRITAIN (I)

By R. BRIGHTMAN

IN his presidential address to the British Association at Liverpool in September, "speaking as a professional scientist who has only recently turned amateur", Sir Edward Appleton made generous acknowledgment of the immeasurable debt which science owes to the amateur scientist. This welcome tribute was supported, moreover, by others at Liverpool, notably at the Assembly of Corresponding Societies when Dr. P. M. Butler, for example, referring to the work of amateur naturalists in Lancashire, particularly in botany, and especially around Manchester and Oldham early in the nineteenth century, pointed out that before 1850 some of these amateurs had an international reputation, especially in the study of mosses. An account of the work of some of these men was given by Mr. J. Cash in his book "Where There's a Will There's a Way", published in 1873¹. The tradition persisted well into this century. Mr. F. E. Milsom, for example, a chemist who died in December 1946, after many years service at Huddersfield in the British Dyestuffs Corporation and the Dyestuffs Division of Imperial Chemical Industries, Ltd., had an international reputation for his study of the bryophytes, and particularly the hepatics; from 1934 he was the referee of the British Bryological Society for British and European hepatics, and he also was an authority on the mosses.

Nevertheless, for the past half-century or so many comments have been made on the decline of the amateur in science, both in numbers and importance. In his presidential address to the British Association at York in 1906², Prof. E. Ray Lankester, for example, regretting this decline, remarked that the field naturalists seemed then not to be so numerous and active as formerly, and suggested that the organization and professional character of scientific work were to a large extent the cause of this decline in its attraction for the amateur. His comment that the mechanics' institutes and lecture societies of the days of Lord Brougham had given place to a very large extent to other entertainments, more diverting, but not really more capable of giving pleasure than those in which science was popularized, and that the decadence was also "due in some measure to the increased general demand for a kind of manufactured gaiety, readily sent out in these days of easy transport from the great centres of fashionable amusement to the provinces and rural districts", has a very topical ring.

In the following year, Prof. H. B. Dixon, in a presidential address to the Manchester Literary and Philosophical Society³, deplored in particular the belief that professional men of science were jealous of the amateur, and by a conspiracy of silence or contempt sought to obscure his merits and so maintain their prestige. Prof. Dixon quoted in this address from a farewell letter written by Dr. Edmund Schunck to the Society some years earlier deploring the increase of the professional element and the disappearance of the amateur from membership of the Society, and making an impressive plea for the cultivation of the amateur in science. The amateur, Prof. Dixon urged, possessed patience, skill and enthusiasm and the advantage of an open mind. He could bring to discussion a freshness of ideas which

more than compensated for any possible defects of critical judgment. Prof. Dixon saw no reason in the nature of things why a professional in one science should not be a successful amateur in another. Probably no more stimulating ideas are struck than at the personal contact of two minds trained in different sciences.

A similar theme was pursued by Prof. H. A. Miers in addressing the Conference of Corresponding Societies at the British Association meeting in Dublin in 1908⁴. While in recent years opportunities for scientific education had expanded, at the same time the gulf between the amateur and the trained scientist had widened, and Prof. Miers was concerned with the possibility of bridging this gap through the work of the corresponding societies and in other ways. Even then it was, he said, more difficult for the amateur to get adequate insight of the recent advances of science without a course of special reading or without attempting to master treatises for which he required some kind of preliminary training. Moreover, the intelligent amateur no longer necessarily belonged to a class quite outside scientific circles as formerly, but was frequently quite learned in one branch of science though he may be the merest amateur in another. Yet when he travelled outside his own subject he was in danger of being placed in a position somewhat similar to that of his predecessor, the amateur of sixty years ago. Not only was the position of the amateur unsatisfactory in regard to scientific literature, but still more was it true as to the societies. The scientific societies were becoming highly specialized in their membership, and it was more difficult for even the intelligent amateur to gain anything from the proceedings and meetings of these societies. In this situation, which is more intense to-day, Prof. Miers thought that the best hope of improvement lay in the work of the local societies, and particularly in the sort of field-work which they could initiate, so that the professional and the amateur could find common ground. Anything, he urged, that tended to break down the barrier between the professional and amateur, between expert and layman, was for the good of scientific progress, and he referred in this connexion to a previous protest by Mr. Lamplugh, president of the Yorkshire Naturalists' Union, against the unhealthy distinction between amateur and professional and his plea for the amateur spirit in scientific work.

Nearly twenty years later, addressing the Conference of Delegates of Corresponding Societies at Oxford in 1926⁵, Sir John Russell remarked that although the amateur with a few shilling's worth of apparatus was no longer able, in Faraday's words, "to make himself as considerable" as people with long specialized training working in well-equipped laboratories, the amateur who was prepared to take trouble still had his place in the advancement of knowledge. In the observational sciences—botany, geology, anthropology, archaeology—he was able not only to interest himself but also to help others. Sir John proceeded then to discuss the scope which regional surveys offered for the activities and wide outlook of the amateur worker. Like other scientific

work such work was team-work, but such as the corresponding societies could do, usually, best in consultation with the professional workers of the university schools. A regional survey gave a survey of a district as an environment for human beings—an account of its physical features, its natural characteristics, its flora, fauna, etc., culminating in a study of the ways in which they affect human life and activity. It was this human aspect that gave the non-professional worker his opportunity, for his close touch with human affairs enabled him to appreciate and to express the human point of view.

Experience of the numerous regional surveys of recent years has amply confirmed the truth of Sir John Russell's remarks. Nevertheless, in spite of this and the long tradition of the amateur worker, particularly in botany, both Dr. R. S. Bates in his book, "Scientific Societies in the United States", and Prof. A. D. Ritchie in a contribution to the symposium "Science, the Universities and the Modern Crisis" of the Manchester Literary and Philosophical Society, could note a tendency for the specialist to despise and ignore the amateur. Prof. Ritchie pointed out that there used to be an enlightened public of amateurs to which every specialist had to appeal to earn recognition. "Now," remarked Prof. Ritchie, "amateurs are unwanted, get snubbed if they interfere and have mostly died off."

There is, however, now less danger of the amateur tradition in science dying out than there was in the early years of the century. Since the War there has been an encouraging increase in the activities of the amateur scientist, particularly in biology, in many countries. Notably in the United States, serious efforts are being made to foster the work of the amateur scientist, and to see how his contribution to the advance of science can be made most fruitful. This tendency is to be welcomed on several grounds. As the title alone of Dr. Dorothy Stimson's book "Scientists and Amateurs" reminds us, the Royal Society began with amateurs. Even earlier than that date, as Canon O. E. Raven pointed out in his study of the making of the modern world, "English Naturalists from Neokam to Ray", there were scientists who could be clearly described as amateurs. Indeed, in his more recent Gifford Lectures, "Natural Religion and Christian Theology", Dr. Raven argued that Robert Hooke was the first professional scientist in Britain. Moreover, particularly in his book on the English naturalists, Raven insists that Bacon and those Christian thinkers who followed him and founded the Royal Society were not primarily concerned with the benefit of their discoveries to mankind. Their basic conviction was that from the accurate understanding of the Creation they could gain a true and effective knowledge of the Creator, and so could bring the life of mankind into a fuller and more intelligent correspondence with His will. They regarded theory and practice as inevitably interdependent. This appeal to factual evidence, to observation and experiment, marks, as Raven shows, a revolution in the method of philosophy which had prevailed until then, which is perhaps even more strikingly illustrated in the life and writings of the Norfolk doctor and naturalist, Sir Thomas Browne, best known for his "Religio Medici". The coming of this modern scientific outlook was, in fact, not just a succession of specialized workers, but was characterized by a general change in outlook among educated men, which is perhaps better appreciated when illustrated in ordinary men

such as Sir Thomas Browne, rather than among those men of genius who were the effective leaders of the Royal Society during its first generation.

Both in this book and in his Herbert Spencer Lecture¹¹, Raven lays much stress on this aspect. These first scientists were not only men of deep religious conviction, but also were possessed of a genuine passion to see life steadily and to see it whole, and of a no less genuine belief that in studying the works of creation they were enlarging man's knowledge of the wisdom of God. Their motive was not solely utilitarian. They cared profoundly for the well-being of their fellows and the benefit which a truer knowledge and wise use of resources would bring. But they were also fascinated by the sheer interest of their explorations, and convinced that in the search for deeper understanding they had a worthy creative bond. That, I think, well expresses one reason why it is important to-day that the amateur tradition in science should be maintained. It is a corrective, as well as an inspiration, to science itself, apart altogether from its contribution to the atmosphere or climate of opinion in which alike the prosecution of scientific work and the application of its results are most fruitful.

Amateurs in science then, in the accepted sense of the word, denoting those that practice their art not as a livelihood, but for the love of it, were to be found in many places and in many classes of people in the latter part of the seventeenth century—mainly in circles sufficiently wealthy or leisured for its pursuit. The other period of this feature which may be noted here is that to which Ornstein directs attention—the way in which unions of scientific workers became the dominating feature of scientific work. They concentrated, he points out, groups of scientists at one place, who performed experiments and carried out investigations impossible to individuals. They encouraged individuals and gave them opportunity and leisure and financial support for scientific work, becoming centres of scientific information and publishing and translating books; they dispelled numerous popular errors and at times endeavoured to reach the general public by means of lectures. They were concerned with trade and commerce as well as science. To them also was due the development of the scientific laboratory, the creation of national observatories, and the standardization and improvement of instruments and technique.

Nor is it surprising to find that the amateur is equally prominent in the eighteenth century, and with, for example, clergyman like Stephen Hales or medical men like John Mayow, who made important contributions to our knowledge of the gases of the atmosphere. As F. Sherwood Taylor pointed out in a paper on "The Teaching of the Physical Sciences at the end of the Eighteenth Century"¹², almost the only scientific professions were those of the medical man and, to a less extent, the engineer, mechanical or military. The professional scientist, in to-day's sense of the word, scarcely existed until the nineteenth century was advanced.

What merits notice here is the way the amateur tradition persisted well into the nineteenth century even when the professional scientist had well established himself outside the ranks of the medical men or the engineers. It is less surprising that as the century opened Edward Jenner (1749-1823) should be scarcely more distinguished as the discoverer and pioneer of vaccination than as the naturalist who gave the first detailed and accurate account of the

eviction by the newly hatched cuckoo of the eggs and fledglings of the foster parents, and even communicated to the Royal Society just before his death important observations on the migration of birds. At the end of the century, however, we can point to Sir John Evans (born in the year of Jenner's death), the professional chemist and paper manufacturer whose amateur interest in geology and archaeology won him as much distinction, including the fellowship of the Royal Society, as his original field of study. Sir Joseph Prestwich, with whom Sir John Evans was first associated in investigations of flint implements in old river gravels, was a wine merchant who took up geology as an amateur before he ultimately became a professional geologist and professor. Sir Charles Lyell, General Pitt-Rivers, Sir John Lubbock and Sir Norman Lockyer (the first editor of *Nature*) are others of the same period who first distinguished themselves in science as amateurs, and only in the latter part of their careers could Lyell or Lockyer be fairly described as professional geologist or astronomer.

The most important point, however, is brought out not so much by the fact that men trained in one profession or in one branch of science can make distinguished and important contributions to the advance of knowledge in quite another sphere which they took up for its own intrinsic interest to them. Particularly where it is a matter of two different scientific disciplines, it could then be argued that one serves as a basis for the other, and that we are concerned with transfer from one professional discipline to another rather than with a strictly amateur activity. The amateur aspect is none the less important, but its value is perhaps seen more clearly in the contributions which came, especially in the first half of the nineteenth century, from Hugh Miller, the journeyman mason of Cromarty, whose "Old Red Sandstone" is essentially the work of an amateur geologist, or the amateur naturalists of Lancashire already mentioned.

Sir John Mand also referred to this aspect in a recent address on the "University Graduate"¹⁸. Sir John referred to a characteristic which is very difficult to describe but which is of special value to-day, and he described it as the mark of the amateur in the best sense of the word—the amateur who does not claim to be a professional or an expert and who, where there is need of expert knowledge, knows that he must consult the professional, but also knows that having consulted him he may well be right not to take his advice; the amateur who loves his job, without sentimentality, and really enjoys his working hours so that there is no clear distinction between the good life as it is lived while he earns his livelihood, and the good life that is lived during his so-called leisure.

This outlook or quality of the amateur accordingly, quite apart from the direct contribution which the amateur scientist can make to the advancement of knowledge, is thus of value in correcting the fragmentation of modern life and in encouraging that wholeness of living which the modern world greatly needs. At the philosophical level it is unlikely that the amateur has any significant contribution to make, but at the practical level of human ecology, such as finds expression in the writings of Dr. K. E. Barlow and others, the multiplicity of amateur activity in varied fields of science could do much to restore sanity to civilization and encourage the receptivity which determines so largely the adjustment of society to a changing environment. In this connexion it is pertinent to recall that industry itself

in the nineteenth century owed something to the amateur. W. Weldon, the journalist, whose interest in industrial chemistry led him to the discovery of the process bearing his name for the regeneration of manganese dioxide in chlorine manufacture, is perhaps the outstanding example. The discovery revolutionized the industry, and Weldon himself was elected a fellow of the Royal Society in 1882. Modern steel-making is founded upon three British inventions, all of which came from outside the industry. The Bessemer and Siemens' converter and open-hearth processes for making steel as it is known to-day both depended on the iron ore used being almost entirely free from phosphorus. The basic process which made phosphoric ores suitable for steel-making was invented by S. G. Thomas, a Metropolitan police court clerk: as a Middlesbrough ironmaster put it, "An amateur pressed it upon the ironmakers".

As has already been said, important contributions to scientific knowledge are still being made by amateur scientists in various fields. At the annual general meeting of the Edward Grey Institute of Field Ornithology, Oxford, on October 27, 1950, Dr. D. Lack, its director, referred to major advances in five fields of zoology in which the amateur naturalist as well as the professional zoologist had participated¹⁴. First, Prof. W. Rowan, speculating and later experimenting on the immediate factors causing birds to migrate, discovered that increased day-length can bring the sexual organs to maturity outside the normal breeding season, and even in midwinter. This has led to important advances in reproductive physiology, not only in birds but also in other vertebrates.

Secondly, the apparently trivial 'splitting' of the bird taxonomists eventually provided a firm basis of comparative material for the subspecies concept, which led in turn to the dramatic discovery of two subspecies of the same species (the great tit), living together in the same region and "behaving as good species".

Thirdly, the field-study of bird behaviour led first to a purely ornithological discovery, Eliot Howard's theory of territory, and later, assisted by observations on captive birds, to important new concepts concerning the nature of instinctive or innate behaviour in animals. The studies started by Lorenz and Tinbergen on birds have later been most profitably extended, particularly to fish and to insects.

Fourthly, bird-ringing has put the study of migration on a precise and quantitative basis, while the recent observations on visible migration and some spectacular results with homing experiments have renewed speculation on the method or methods by which birds find their way.

Finally, there is the new study of "population dynamics", or "population ecology". Through long-term censuses, the fluctuations in certain bird populations are more accurately known than those of any other animal. An unexpected by-product of the bird-ringing scheme has been to establish not only how long wild birds are capable of living, but also their average expectation of further life. The latter is far shorter than popularly believed—only about one year in the case of the robin, for example. The reproductive-rate of birds and the factors determining it have also been the subject of precise and quantitative study. Indeed, it should soon be possible to obtain a complete life-equation for a bird living under normal conditions, and this should help to advance the study of the factors which control population density in animals.

The co-operative field-work of the British Trust for Ornithology, which was founded in 1933 to maintain the field-work already started at the University of Oxford between the professional zoologist and the amateur, is of some interest in this connexion. It should be remembered, of course, that, as Mr. Bruce Campbell has pointed out¹⁰, very similar co-operative methods were used by the British Association and by the British Ornithologists' Club in their studies of bird migration many years ago, and we may even see the germ of the idea in Gilbert White's circle of correspondents. In a co-operative inquiry, observers all over the country are linked together by a central organizer, to whom they send in their information, and who is responsible for drawing up the final report and for calling in expert advice as he requires it. It has been a feature of inquiries run by the Trust that the organizer has seldom been a professional zoologist, but that the inquiry has been agreed upon and the report submitted to a research or advisory scientific committee, on which sit both professional (*sensu stricto*) zoologists and men who have devoted the free hours of a lifetime to studying birds. Usually one or two members are particularly interested in each inquiry and keep in close touch with the organizer.

Careful choice of subject in such inquiries is, of course, required, and the manner in which it is conducted may also be modified. An organizer may conduct his inquiry through a limited group of correspondents of proved experience, or he may delegate to local organizers, who can sieve information in their own regions before sending it on to him. A good example of this is the ten-year census of the great-crested grebe, over a sample area mainly in the English Midlands, which began in 1946 as a follow-up to the original national survey of 1931.

The co-operative technique has not only been used for bird problems. In Monica Shorten's study of the status of the grey and red squirrels in Britain¹¹, a research worker at the Bureau of Animal Population, Oxford, corresponded with voluntary observers all over the country, while Sir William L. Taylor's surveys of the distribution of wild cats, capercaillie and wild deer on Forestry Commission areas¹² have shown how the staff of a widespread organization can contribute useful data as a by-product of their main work.

The above contributions to zoology have been made partly by professional and partly by amateur naturalists. Both, it is scarcely necessary to add, are scientists. The cleavage imagined by some nature-writers to exist between the cold-blooded scientist and the warm-hearted amateur is, of course, a fiction. Thus the amateur scientist still continues to add materially to ornithology. Incidentally, it may be noted that in his book, "The Art of Scientific Investigation"¹³, Prof. W. I. B. Beveridge remarks, "I have noticed that in England a great many research workers in both the biological and non-biological sciences are, or have been in their youth, keen naturalists. The pursuing of some branch of natural history as a hobby by a young man may be a valuable indication of an aptitude for research".

At the Birmingham meeting of the British Association, in a paper read to the Education Section, Dr. A. G. Lowndes quoted two instances of research carried out at schools in spite of the absence of costly apparatus¹⁴. A wave passing up a flagellum was first photographed, not at the University of Cambridge, but at Marlborough College. The myth

that the egg of the dogfish consists of an enormous amount of yolk was not exposed and exploded at a university. The initial work was done at Rugby School during ordinary class teaching. A promising feature of recent years is, in fact, the extent to which opportunities are opening up for effective participation by young amateurs in scientific work. The observations on the natural history of starlings, recording the results of twenty-five years bird ringing at Bootham School, York, under the direction of Mr. Clifford J. Smith, is one example of activities which the British Trust for Ornithology has done much to foster during the past twenty years. The survey has shown that in winter we have starlings of two races in Britain: the residents that nest here and those that come from Europe but nest abroad and cannot interbreed with our native birds. Only a preliminary report is yet available, but it is hoped that much of the survey will be published in more permanent form.

Another example of what enterprise and imagination can do to demonstrate the nature of scientific work to the schoolboy and to provide opportunity of participating in the making of observations of value to science is to be seen in the oceanographic expedition to the North Sea organized early in 1953 for science sixth-form boys from the Watford Grammar School¹⁵. The expedition consisted of eleven boys and one master, and the party was distributed among the trawlers so that in each ship there was one boy who carried out the duties of a biologist and one who acted as chemist, physicist and meteorologist. The biologist was to collect otoliths and connect their age with their length and to investigate the stomach contents of as many fish as possible. The others were to study the trawl contents to gain information about the North Sea as it was in the last glaciation and during the subsequent emergence of dry land, and build up a complete picture of the conditions of North Sea fishing. The party obtained fifty-two samples of salt water and 130 sets of meteorological recordings, including surface temperature, relative humidity, wind, sea, swell and sounding and position and time.

The venture clearly has features in common with the expeditions of the British Schools Exploring Society, notably that to British Columbia in 1953, on which scientific work undertaken included the mapping of the region of the north-western arm of Lake Stuart¹⁶. Two bathymetric cross-sections undertaken showed interesting results relating to the general form of the lake basin. A main meteorological station was opened at base camp and regular observations were taken, and one team was concerned with the micro-meteorology of the forest trunk-space. Biologists on the expedition made collections of pressed plants and of lesser known insects from the deciduous and coniferous forests as well as from the alpine zone of the Mount Sydney Williams massif. Detailed notes of bird and animal life were also made.

Yet another instance is to be seen in the extensive survey of weather in the Cairngorms conducted in the summer of 1953 at five high-altitude weather stations by teams of undergraduates and senior schoolboys¹⁷. The practicability of camping in such tough conditions—three of the camps were at more than 3,000 ft.—was demonstrated in 1952 by a pilot expedition from the Cambridge University Rover Scouts, and last year's expedition was planned in the light of that experience. All the stations were

at least five miles walk from the base camp at Glenmore Lodge. Weather observation did not take up the whole time after the camps had been made secure against bad weather. Once the camps were established, the observers turned their attention to many other geographical jobs. The Cambridge geographers spent ten days in late June excavating the near-permanent snow patches to obtain cross-sections of the banding in the snow. Another team was able to study and map beautiful miniature sand spits by their camp at Loch Avon. More than a hundred people were involved in this survey, but the vast amount of information collected only covers a small part of one year. In future it is hoped to obtain more samples of the weather in the Cairngorms, probably extending the survey into other seasons. This work, of which a full report is to be published, should appeal particularly to schools.

A similar but even more interesting development, from the point of view of the young amateur scientist, is the growth of the Tarn Survey Project of the summer of 1947, when Brathay Hall was first opened as a holiday centre for boys from industry, into the Brathay Exploration Group in 1950. The idea originated when Brian Ware, while deputy warden of Brathay Hall, was told by Vaughan Lewis, of the Department of Geography of the University of Cambridge, of the absence of detailed information about the depths of the tarns in the Lake District, and the serious obstacle it constituted to research on glacial erosion in the District. The challenge of this relatively simple but real task of exploration led to the organization, in August 1947, of an expedition to Easedale Tarn, followed later by a second expedition to Angle Tarn under Bowfell, for which purpose a new collapsible and portable boat was devised. The success of these two expeditions encouraged the organization of a more ambitious expedition in the following year to Bleawater, and from that time the principle of recruiting boys equally from schools and industry became the basis for future developments, and the principle of using a mountain camp as base was established. It also proved the value of recruiting junior leaders for expeditions from among university undergraduates. Four other parties were organized in August and September 1949, and for the following year plans were laid on the assumption that Brathay Hall itself would again be the base for expeditions. It was also realized that if the Tarn Surveys were to take on a permanent and useful form, suitable separate headquarters would be needed, and the survey would require broadening to include a wide range of field-study. The 1950 surveys in the Lake District were handicapped by bad weather, but notwithstanding, successful surveys of three tarns were made, and an expedition to the Jotunheim Mountains in Norway was also organized, where the members undertook definite tasks in a programme of research organized by the Department of Geography at Cambridge. From a base-camp set up at Vindal, one party carried out a plane table survey of the glacial features of a corrie, under Glittertind, which had not previously been mapped in detail, and made observations and measurements to determine the nature of a large ice apron in the corrie. The second party carried out a detailed sounding of Juvatnet, a lake lying under the ice cliffs of the Kjeldan corrie glacier.

The following year marked the transition from the Tarn Surveys, run as part of the 'Holidays with Purpose' scheme, to the fully constituted and self-

contained Exploration Group. The new headquarters could not be built during the year; but the programme of field-work included the detailed charting of five more tarns and some preliminary work on tarn temperature régimes, and in freshwater biology and botany. Previous experience had indicated that a party of eight boys and two leaders was the largest practical unit for field-work, and that by far the most successful parties were those in which schools and industry were equally represented, and in which individual schools and firms were represented by one or two boys rather than by three or four, and in which there was a nucleus of boys who had been members of at least one previous expedition. During this period, 1947-51, more than 250 boys participated in the expeditions and a panel of some thirty voluntary leaders was built up, while twenty tarns were charted for the first time.

The following year, 1952, the first in which the new headquarters in the Brathay Estate were available, four expeditions in the Lake District were organized, one surveying Codale Tarn and Hayswater; another to Angle Tarn above Patterdale; a third to Watendlath Tarn; and a fourth to Sty Head Tarn. There was also organized an expedition to the Jotunheim in Norway; but bad weather severely curtailed the major projects for a temperature survey of Juvatnet, and tunnelling through the firm of the Kjeldan corrie glacier.

In the summer of 1953 three of the four expeditions commenced an intensive survey of the Bleawater corrie, under High Street, including the temperature régime, a study of the geomorphology of the corrie, including the making of an accurate profile from the ridge of High Street, through the main and lower corries, to the Haweswater valley; a profile of the neighbouring Riggindale; and an examination of the widespread and varied evidence of glaciation, and a study of the meteorology of the corrie, including particularly an investigation into the wind circulation as well as a pioneer botanical survey. The fourth expedition was divided into two groups, one of which undertook a temperature survey of Easedale Tarn and the other a survey and sounding of Burnmoor Tarn, which does not lie in a corrie. In August 1953 a third expedition went to Norway to complete the work carried out on the previous year, including the completion of the tunnel and the exploration of the *randkluft* below its inner end; an examination of the well-developed stone rings lying around Juvasshytte; and a survey of plants, from the almost barren plateau at just over 6,000 ft. down to the tree line at about 4,000 ft. In the same month an expedition was arranged to Iceland which, although independent, maintained close liaison with an expedition from the University of Cambridge. From the base camp at the north end of Kaldidalur a weather station was set up at an altitude of 3,900 ft. A plane-table survey of a volcanic crater was made on a scale of 1/5,000, while another party surveyed by compass and 100-ft. tape an ice-margin lake—Thorisdalurvatn—on the east side of Thorisdalur. From the base camp a vertical soil section 11 ft. deep was dug in a stream bank, and a plane-table traverse with aneroid heights was made of the Geita from Kaldidalur to the Hvita Plain.

Under expert guidance, the amateur archaeologist also frequently helps his professional colleague. In 1951, for example, a broadhead three-note bone whistle dated from the Iron Age was discovered by members of a Study Course in Field Archaeology at

the Malham Tarn Field Study Centre in excavating a burial site between Gordale Beck and the road to Malham Tarn.

MINERAL DRESSING AT THE ROYAL SCHOOL OF MINES, LONDON

WITHIN recent decades the increasing industrial demand for engineering metals and non-metallic minerals has led to the exploitation of mineral deposits too low in grade or too complex in ore structure to be profitably worked by the simpler methods in use thirty years ago. Though the demand still rises steadily, most of the older deposits are already in full production or even approaching exhaustion. Difficulties of climate, power, access and mechanized mining have been overcome to a gratifying extent; but the extraction of small quantities of valuable material from a large amount of associated host-rock still presents many difficulties.

In addition to modernized developments of the older methods of mineral dressing, in which gravity, ferromagnetism, electrical conductivity and the skill of the hydro-metallurgist are exercised, the process of froth-flotation has grown in importance. It provides the only method of concentration in many

ore-dressing plants, and is used at some point in most of the others. The process is applied to finely ground ore pulped with water. Each ore particle must be so small that its settling velocity is of the Stokesian rather than the Newtonian order. There are two main reasons for this: first, the separation of value from waste depends on differences between the surface tensions of the particles undergoing treatment, and these differences cannot be exploited if the masses of the reacting particles introduce a high gravitational pull; secondly, the desired particles must be freed by grinding from those which are to be rejected, and this liberation is only effective when a substantial part of the ore has been ground well below 50 μ . Particles only a few microns in diameter are usually responsive to treatment.

Liberation by wet grinding is practised under close physical control. The prepared ore-pulp next receives small additions of chemicals which control flocculation, detergency and the surface characteristics of the various minerals in aqueous suspension. The pH must be held within defined limits during the whole of the treatment. A copious supply of air-bells is next blown through the pulp. As a result, particles which are relatively aerophilic are attracted into the interface between water and air and rise to the surface of the pulp where, with the help of a suitable frothing chemical, they form an unstable mineralized froth which is removed from the system. Huge tonnages of ore are treated daily along these lines.

In recognition of the vital importance to industry of a trained scientific outlook in developing and operating such processes as the one outlined above, the University of London instituted a degree course in mineral dressing in 1952. This is a B.Sc. option (engineering) in metallurgy, and it carries with it the associateship of the Royal School of Mines. On March 17 the new laboratories built in connexion with this degree course and its associated research

Fig. 1. Crushing room. Right, jaw crusher, Symons cone crusher, set of rolls, automatic sample splitter and a Sherwen screen; left, small crushing machines. Ore is moved by electric crane and mono-rail.

Fig. 2. Small wet-grinding mill in closed circuit with an Atkine classifier

activities were 'at home' to visiting scientists, when a comprehensive range of dry-crushing, wet-grinding and sampling machines were demonstrated. All the machines are protected by a dust-control system which permits virtually all the rock treated to be recovered in the end-products. The crushing section is under negative pressure, so that the main testing laboratories are not contaminated by air-borne mineral dusts. In the research section, which is reached through air-locks, all air is spray-washed and filtered before entry, the block being kept under a slight positive pressure to ensure freedom from similar contamination. These precautions have been taken because in the atmosphere of South Kensington a freshly sheared mineral surface receives sufficient hydrocarbon coating from the air in a minute or less to make its surface reactions quite unreliable. Under the new air control, not only the materials being tested, but also the reagents and apparatus, remain chemically clean for reasonably long periods.

During the 'at home', some standard ore-dressing operations were demonstrated, either on a miniature scale or as pilot-sized operations such as are conducted in commercial plants. Exhibits were also arranged to show something of the research work now under way in the special laboratories. These included the use of supersonic waves to influence sorption-rate from the water phase through the zeta-zone to immersed mineral surfaces; pressure-leaching as a hydro-metallurgical method of direct extraction of metals in the form of soluble salts; sub-sieve sizing by sedimentation and elutriation; radiotracer equipment to be used with fatty acids in the study of sorption phenomena at mineral surfaces; identification of minute quantities of unknown minerals by a combination of selective separation and micro-chemistry; thin section radiography for micro-examination of minerals and mill products; a motor-driven stage and counting machine for quantitative assessment of particle types under the

microscope; and a comparatively new method of testing the surface condition of small particles. Although the operations shown were limited by considerations of suitability for rapid demonstration as well as by the fact that the research work is only now settling down in its new home, it is clear that a wide field of scientific investigation has yet to be surveyed in terms of the special requirements of the mineral industry, and that measures have been taken to correlate this work with its commercial utilization. In this connexion, the traditional policy of making suitable provision for industrial ore-testing at the Royal School of Mines has been retained, so far as considerations of space and staffing permit.

One overriding justification for the new degree course and its allied activities

is the shortage of suitably trained mineral-dressing engineers. This dearth has proved a restrictive factor in the development of the large low-grade deposits on which modern industry increasingly depends, and is felt in every part of the world. During the next few years the Mineral Dressing Section of the Royal School of Mines expects to meet part of this need by giving accelerated training to postgraduate students; but it is felt that the long-term answer involves a steady increase in the number of graduates specially trained in this subject. Since much of the work can be done in the mill laboratory under pleasant, interesting and clean conditions it is not proposed to restrict intake to men only, though all those entering must be prepared to spend the first few years of their working careers outside Great Britain.

E. J. PRYOR

OBITUARIES

Lady Robinson

THE death of Gertrude Maud Robinson, wife of Sir Robert Robinson, Waynflete professor of organic chemistry in the University of Oxford, came as a profound shock to chemists throughout the world, and in particular to those in many universities who have been privileged to know her. Her contributions to chemical knowledge have been substantial in spite of many pressing calls on her time and energy. With characteristic enthusiasm she was working in the laboratory a few days before her death, and it is in the dual role of an indefatigable research worker and a kindly hostess that she will long be remembered. In particular, the younger members of the teaching staffs and their wives have reason to be profoundly grateful to her; she found time to take a personal interest in them and their families, which lasted long after they moved elsewhere. One other aspect of her

devoted life must also be mentioned. To her must be due in no small measure the unique position which Sir Robert holds to-day among the chemists of the world.

On January 21 of this year, Lady Robinson's contributions, direct and indirect, to organic chemistry were recognized by the award of the honorary degree of Master of Arts of the University of Oxford, a gesture which warmed the hearts of chemists everywhere.

Lady Robinson's scientific papers, mainly in the *Journal of the Chemical Society*, record work carried out in the Universities of Manchester, Sydney, Liverpool, St. Andrews, London (University College), and the Dyson Perrins Laboratory, Oxford. The first two, with Dr. C. Weismann, were published in 1910 and 1911 under her maiden name of Walsh. Many of the later papers were published jointly with Sir Robert Robinson. In work on certain derivatives of catechol ethers, the important discovery was made that asymmetrical substitution occurred in azoxy compounds, thus adding proof to that earlier provided by Angeli of the asymmetrical structure of the azoxy compounds themselves. Another series of papers of considerable novelty dealt with nitrogenous pseudo-bases, and the mechanism of Fischer's indole synthesis. Still another series described the development of new methods for the synthesis of high-molecular weight fatty acids, notable among which was a variation of the acetacetic ester synthesis for the extension of the carbon chain by twelve carbon atoms at a time; this elegant process culminated in the synthesis of *n*-triacontanoic in 1934.

Lady Robinson published numerous papers on the anthocyanins and their separation by distribution between two partially miscible solvents, a method which was virtually a forerunner of modern partition chromatography. More recently still, her interest in these compounds led her to undertake a very difficult task, namely, the investigation of the leucoanthocyanins, in particular peltogynol. She took an active part in the work on penicillin during the Second World War, and it is perhaps not generally known that she was the first chemist to prepare synthetical material with genuine antibiotic character of the penicillin type.

Lady Robinson's name is assured of a lasting and honoured place among those organic chemists who have made major contributions to their science.

W. BAKER

Prof. E. Esclançon

We regret to record the death on January 28 of M. Ernest Esclançon, the *doyen* of French astronomers, at the age of seventy-seven.

Esclançon started astronomical work at Bordeaux in 1899, taking a regular share in the routine work of the Observatory, observing minor planets and comets and making observations with the meridian circle and equatorial. But although he remained throughout his life associated with observatories, his principal achievements were not in astronomy, apart from administrative work. While still at Bordeaux he carried out gravity determinations in south-west France, relative to the standard at Paris. After the outbreak of war in 1914, he assisted in the geographic service of the French Army, doing work on sound-ranging and making a study of the sound waves resulting from the firing of a gun and the passage of a shell through the air. Towards the end of the First World War he took part in researches concerning submarines.

In 1919 Esclançon was appointed director of the Observatory at Strasbourg, which had been taken over from the Germans. Here he had the opportunity of publishing the work he had done during the War and of extending his researches to such subjects as the zones of silence at various distances from explosions, the rotation of projectiles around their centre of gravity, and the tides. He was so successful in building up an effective observatory at Strasbourg that when Deslandres retired from the directorship of the Observatories of Paris and Meudon in 1929, he was appointed to this important post.

Esclançon was always interested in the time service in which Paris has for long played an important part. He developed methods for the synchronization of pendulums electrically, and he introduced the speaking clock which latterly gave accurate time signals to 16 million Parisians annually. After acting as host for the general assembly of the International Astronomical Union at Paris in 1935, he was elected president of that Union for the next three years, terminating with the congress at Stockholm in 1938. He was president of the Paris Academy of Sciences in 1942, and finally retired in 1946. His services to astronomy were recognized in Great Britain by his election as an Associate of the Royal Astronomical Society in 1932.

J. JACKSON

NEW FELLOWS OF THE ROYAL SOCIETY

At the meeting of the Royal Society on March 18, the following were elected to fellowship:

PROF. D. H. R. BARTON, professor of organic chemistry, Birkbeck College, London, distinguished for his fundamental contributions to the chemistry and stereochemistry of terpenes, triterpenes and steroids.

PROF. T. MACF. CHERRY, professor of mathematics, University of Melbourne, distinguished for his researches on transonic flow and for earlier work on orbits in celestial mechanics.

PROF. E. G. COX, professor of inorganic and physical chemistry, University of Leeds, distinguished for his contributions to stereochemical problems in inorganic and organic chemistry by the application of X-ray crystallographic methods.

DR. F. O. FRANK, reader in physics, University of Bristol, distinguished for his original contributions to theories of crystal growth, of plastic deformation and of dislocations in crystalline solids.

PROF. A. B. HILL, professor of medical statistics, University of London, distinguished for his work on the application of statistical methods to medical problems, including the evaluation of new therapeutic and prophylactic drugs.

PROF. E. S. HILLS, professor of geology and mineralogy, University of Melbourne, distinguished for contributions to palaeontology, particularly of Devonian and Tertiary faunas, and for geological studies in Australia.

SIR CHRISTOPHER HINTON, managing director, Industrial Group, Department of Atomic Energy,

distinguished as an engineer who, by his leadership and by direct contributions, has played a major part in the development of large production plants in the British Atomic Energy Project.

PROF. F. E. KING, professor of chemistry, University of Nottingham, distinguished for his original contributions to synthetic organic chemistry, and for his investigations on wood extractives.

DR. H. G. KUHN, lecturer in physics, University of Oxford, distinguished for his development of delicate interferometric techniques, his work ranging from the study of continuous spectra to the examination of hyperfine structure.

DR. H. W. LISSMANN, assistant director of research, Department of Zoology, University of Cambridge, distinguished for his researches on animal behaviour, including the demonstration of a new form of sensory activity in animals.

PROF. F. C. MACINTOSH, professor of physiology, McGill University, Montreal, distinguished for his researches in the physiology and pharmacology of the central and peripheral nervous system, and for methods of biological assay.

DR. L. HARRISON MATTHEWS, director, Zoological Society of London, distinguished for his work on the physiology of reproduction.

J. L. PAWSEY, assistant-chief, Radiophysics Division, Commonwealth Scientific and Industrial Research Organization, Sydney, distinguished for his contributions to techniques of radio and radar, and in particular for his applications of these techniques to radio astronomy and to the study of the ionosphere.

DR. M. F. PERUTZ, lecturer in biophysics, University of Cambridge, distinguished for his elucidation of the structure of complex protein molecules by X-ray diffraction methods; for his detailed study of the structure and properties of haemoglobin; and for his investigations of the structure, deformation and flow of glacier ice.

PROF. A. J. S. PIPPARD, professor of civil engineering, Imperial College of Science and Technology, London, distinguished for his theoretical and experimental contributions to the theory of structures.

DR. ROSALIND V. PITT-RIVERS, biochemist, National Institute for Medical Research, London, responsible for notable advances in the biochemistry of the thyroid gland.

PROF. R. D. PRESTON, professor of plant biophysics, University of Leeds, distinguished for his investigation of the fine structure of plant cell walls.

DR. J. W. S. PRINGLE, lecturer in zoology, University of Cambridge, distinguished for his researches on neuromuscular co-ordination and the mechanism of equilibration in insects.

F. J. RICHARDS, senior principal scientific officer, Research Institute in Plant Physiology, Imperial College of Science and Technology, London, distinguished for his researches on the effects of mineral deficiencies and for his work on developmental morphology in plants.

PROF. C. RIMINGTON, professor of chemical pathology, University College Hospital Medical School, London, distinguished for his work on the biosynthesis of porphyrins.

PROF. W. W. ROGOSINSKI, professor of pure mathematics, University of Durham, distinguished for his contributions to mathematical analysis, particularly in the theory of functions and the theory of series, especially Fourier series.

DR. F. SANGER, biochemist, Medical Research Council, Cambridge, distinguished for his studies on protein structure, especially that of insulin.

PROF. H. G. THODE, head of the Chemistry Department, McMaster University, Hamilton, Ontario, distinguished for improvements in the technique of mass spectrometry and for the application of mass-spectrometric methods to problems in nuclear physics, chemistry and geochemistry.

DR. W. A. WATERS, lecturer in organic chemistry, University of Oxford, distinguished for his researches into the mechanism of organic reactions, especially those involving free radicals.

DR. C. B. WILLIAMS, head of the Department of Entomology, Rothamsted Experimental Station, distinguished for his pioneer work on migration of Lepidoptera and his studies of insect populations.

NEWS and VIEWS

Physics at Cardiff:

Prof. R. T. Dunbar

PROF. R. T. DUNBAR, who retires this summer from the chair of physics in University College, Cardiff, has been associated with the Physics Department at Cardiff for the past thirty years. Following a period of teaching and research at Edinburgh with the late Prof. C. G. Barkla, he was in 1924 appointed lecturer and director of the Viriamu Jones Research Laboratory, Cardiff, and held this position under both Prof. A. L. Selby and Prof. H. R. Robinson. It was during this period that he was able finally to dispose of Barkla's proposed *J* phenomenon. The planning and equipping of the new Tatem Laboratories in Cathays Park, Cardiff, which were then begun, were entrusted to him. Since 1930, when he succeeded to the chair, Prof. Dunbar has devoted himself to the needs of his students and to the increasing demands of a growing Department. During the years of economic depression between two World

Wars and again during the Second World War, the capacity of the new laboratories was fully taxed, so that the accommodation has recently had to be extended once more. The present facilities and equipment of his own Department testify to his vision and energies, but the rest of the College, too, has benefited much from his personal and detailed interest in all aspects of its growth.

Prof. A. J. C. Wilson

PROF. A. J. C. WILSON, who succeeds Prof. Dunbar, has had a distinguished record as an X-ray crystallographer. From Dalhousie University, Nova Scotia, and the Massachusetts Institute of Technology, he went in 1938 to the Cavendish Laboratory, Cambridge, as an 1851 Exhibitioner, and quickly showed an exceptional ability in both experimental and theoretical work. He carried out some beautiful work on the measurement of coefficients of expansion of

metals by X-ray diffraction, but it was apparent that his theoretical ability was his greater gift, and he made several important fundamental contributions to the theory of the diffraction of X-rays by crystals; his work on diffraction by imperfect crystals is likely to remain standard for a long time. He was quick to realize the importance of apparently trivial observations, and a chance remark by one of his colleagues at Cambridge set him thinking along a new line—the distribution of intensity in the different orders of diffraction from a single crystal. Unable to proceed far with this subject during the war years, he took it up seriously upon his appointment as senior lecturer at Cardiff, and, with several of his colleagues, he published a series of papers which have revolutionized ideas about the determination of space groups. The methods described have already proved extremely useful in many crystal-structure determinations. Prof. Wilson has also shown himself to be an extremely able administrator, his work on editing "Structure Reports" and producing data for the "A.S.T.M. Index" alone putting the world of X-ray diffractionists greatly in his debt.

Pharmacology and Therapeutics at Sheffield:

Dr. G. M. Wilson

PROF. E. J. WAYNE is resigning at the end of this month from his post as professor of pharmacology and therapeutics in the University of Sheffield, in order to take up the chair in the practice of medicine in the University of Glasgow, and will be succeeded by Dr. G. M. Wilson, at present lecturer in therapeutics in the University of Sheffield. Dr. Wilson was educated at the Edinburgh Academy and the University of Edinburgh, qualifying as a medical practitioner in 1940. During 1941–46 he served in the Medical Branch of the Royal Air Force, becoming officer in charge of the Medical Division of No. 6 R.A.F. General Hospital, Cairo, and medical specialist to the R.A.F. Middle East Command Medical Board. After demobilization, he was appointed an assistant to the Medical Unit of St. Mary's Hospital, London. He went to the University of Sheffield in 1950 as lecturer in therapeutics and a year later was appointed senior lecturer in therapeutics and a consultant physician to the United Sheffield Hospitals. He spent the academic year 1952–53 at Harvard University on an Eli Lilly travelling fellowship in medicine of the Medical Research Council. Since the War, Dr. Wilson has carried out a series of studies of some disorders of the peripheral circulation, and he has recently been studying the part played by the endocrine system in the development of metabolic and cardiovascular disturbances.

Statistics in the University of Aberdeen

THE University of Aberdeen is creating the new post of reader in statistics as from October 1, 1954. Dr. D. J. Finney, lecturer in the design and analysis of scientific experiments in the University of Oxford, will be the first holder of this readership. Dr. Finney will be in charge of teaching and research in this Department of Statistics, in which new developments, including the provision of increased statistical services for other University departments, are under consideration. The Agricultural Research Council is simultaneously establishing a new Unit, the Unit of Statistics, within the University of Aberdeen. Dr. Finney will be the director of this Unit, and in this capacity will collaborate with Agricultural Research Council institutes in Scotland and assist in the design

and analysis of their experiments. Dr. Finney's advice will also be available to other institutes and organizations concerned with agricultural research in Scotland. In addition, the Unit of Statistics will be responsible for carrying out specific investigations on behalf of the Council. The University Department of Statistics and the Agricultural Research Council's Unit will be housed in Marischal College, Aberdeen.

Royal Geographical Society: Awards for 1954

H.M. THE QUEEN has approved the award by the Royal Geographical Society of the following Royal Medals: *Founder's Medal*, to Brigadier Sir John Hunt, leader of the British Mount Everest Expedition; *Patron's Medal*, to Dr. N. A. Mackintosh, deputy director of the National Institute of Oceanography, for research and exploration in the Southern Ocean since 1924, with special reference to his voyages in the *Discovery II* during 1929–31 and 1933–35. The Council has made the following awards: *Murchison Grant*, to G. R. Crone, librarian and map curator of the Royal Geographical Society, for contributions to the history of cartography and to the history of geography; *Bage Grant*, to Commander G. S. Ritchie, of the Hydrographic Department of the Admiralty, for his contribution to oceanographical exploration as commanding officer of H.M.S. *Challenger* during 1950–51; *Cuthbert Peck Grant*, to Dr. T. E. Armstrong, of the Scott Polar Research Institute, University of Cambridge, for studies in the history and economic development of the Arctic, with special reference to the northern sea route; *Gill Memorial*, to Dr. W. G. V. Balchin, lecturer in geography, King's College, London, for contributions to geomorphological and geographical research; and *Mrs. Patrick Ness Award*, to C. W. M. Swithinbank, Pembroke College, Oxford, formerly a member of the Norwegian-British-Swedish Antarctic Expedition, 1949–52, for research in antarctic glaciology.

British Welding Journal

WITH the co-operation of the Institute of Welding and of the British Welding Research Association, a new monthly periodical, the *British Welding Journal*, has been started, and the first part has just been published (2 Buckingham Palace Gardens, London, S.W.1. Members, free; non-members, 10s.). As Dr. J. H. Paterson, a past president of the Institute of Welding, remarks, "when it is considered that the first practical applications of the welding of metals on any considerable scale are not much more than sixty years old, it is remarkable how rapidly this process has attained its present proportions". All aspects of the subject are undergoing intensive scientific and technical investigation, and it is to provide a unified avenue of publication for such work that the new *Journal* is primarily intended. This combination of the proceedings of the Institute of Welding, in the main practical in character, and the scientific reports of the Welding Research Association, together with reviews of current literature, should, in the words of Sir William Larkie, "make available to the technologist the results of research, so that they can be translated into practice; and bring to the knowledge of the research worker the difficulties which arise in their practical application". Among the papers contained in this first issue are the following: a most interesting historical account dealing with the development of

metal-arc welding and electrodes during the past half-century; welding as a career; the welded structure in a pump-house foundation; the effect of steel quality on spot-welding properties; and the use of self-adjusting arc equipment for welding a light-alloy deckhouse. The presentation of the *Journal* is excellent, permitting photomicrographs to be reproduced with admirable clarity. It should perform a most valuable function in a sphere of metallurgy and engineering which is bringing about a revolutionary change in the constructional field.

A Systemic Rust Fungus

WHEN the uredospores of the autoecious rust *Puccinia suaveolens* attack the creeping thistle *Cirsium arvense*, isolated uredo-pustules, usually with some teleutospores, are formed (B. P. Manziac, *Ann. Bot.*, N.S., 17, 68 and 551; 1953). The mycelium later grows down into the roots and becomes systemio. In some of the root-buds the mycelium appears unchanged and bears uredosori; in others it undergoes a somatic segregation of mating type and bears spermogonia only. Teleutospore germination is so erratic that basidiospore infection is responsible for only a small amount of the spermogonial infection observed. The spermogonial mycelium in the systemically infected shoots is heterothallic, and there are two mating types. All the spermogonia on one shoot bear spermatia of only one mating type. Therefore, segregation of mating type must take place at the base of the shoot or even in the roots. The multinucleate condition of the mycelium in both uredosoral and spermogonial shoots makes it impossible to observe segregation directly.

Common Marine Bivalves of California

A GUIDE to some sixty species of Californian lamellibranch molluscs of economic importance has been compiled by John E. Fitch and published under the title "Common Marine Bivalves of California" (Fish Bulletin No. 90 of the Department of Fish and Game, State of California; pp. 102; San Francisco, 1953). The first twenty pages contain general information on nomenclature, habits, structure and reproduction of marine bivalves, and also give methods of collecting, culturing and preparing edible species. Then follows a key for identification of the species, with diagrams to illustrate technical terms. The main section comprises descriptions of the species, a page being allotted to each. A photograph of the outside of the shell is given; but only in the piddocks and gapers are the siphons shown. A brief description of distinguishing characters is accompanied by notes on the range of each species in California, its habits and economic use. A number of species of no economic value, but which may be taken when searching for food or bait, are included. The author has made an attempt to standardize the names by which the commoner bivalves are known, and has found it necessary to change some to accord with their phylogenetic relationships. The style of this pamphlet is clear and concise, and the black-and-white photographs are excellent. Although intended for the amateur naturalist or clam digger, this work has considerable scientific value. The method of presentation might well form a basis for other publications of a similar nature.

University of Leeds: Gifts to Departments

GIFTS made to various departments in the University of Leeds include the following: to the

Department of Physical Chemistry, £700 from the Anglo-Iranian Oil Co., Ltd., for research, and 5,000 dollars from the Rockefeller Foundation for research in radiation chemistry under the direction of Prof. F. S. Danton; to the Department of Textile Industries, £250 from the Anglo-Iranian Oil Co., Ltd., for research; to the Department of Civil Engineering, £500 from the Cement and Concrete Association for scholarships and £200 a year (plus income tax) for seven years from Wm. Airey and Son (Leeds), Ltd., for scholarships in concrete technology; and to the Department of Colour Chemistry and Dyeing, £5,000 from the British Silk Dyeing Co., Ltd., Balloch, Alexandria, Scotland, for research.

Department of Scientific and Industrial Research: Grants to Research Workers and Students

THE Department of Scientific and Industrial Research is offering three types of grants to British research workers and students normally resident in Great Britain: maintenance allowances (approved fees plus £245-325) to postgraduate students for a year's full-time training in the methods of scientific research; senior research awards (maximum of £600 a year) for postgraduate research; and grants for special researches to enable investigators to obtain scientific, laboratory or clerical assistance or to purchase special equipment, materials or services not normally provided by a university for scientific purposes. Generally speaking, candidates for maintenance allowances or senior research awards should not be more than twenty-seven years of age. All the awards are tenable in universities, colleges, establishments of the Department of Scientific and Industrial Research, research association laboratories and other institutions approved by the Advisory Council for Scientific and Industrial Research. The closing date for applications for maintenance allowances is April 15 and for the other awards April 1. Further information is available in a pamphlet, "Notes on D.S.I.R. Grants to Research Workers and Students" (price 6d.), obtainable from the Department at Charles House, 5-11 Regent Street, London, S.W.1.

Colonial Service: Recent Appointments

THE following appointments have recently been made in the Colonial Service: J. R. Antoine (assistant plant pathologist, Mauritius), senior agricultural officer, Mauritius; P. O. Chambers (director of agriculture, Cyprus), director of agriculture, Northern Region, Nigeria; M. Robson (conservator of forests, Nigeria), chief conservator of forests, Western Region, Nigeria; I. Langdale-Brown, botanist, Uganda; J. P. T. Boorman, scientific officer (entomologist), Nigeria; D. N. F. Hall and J. H. Wickstead, scientific officers (fisheries), Singapore; F. H. Talbot, scientific officer, East Africa High Commission; P. J. Larkin, veterinary officer, Kenya; P. A. L. Wight, veterinary officer, Nyasaland; E. F. W. O. Brunig, assistant conservator of forests, Sarawak; N. W. Neal, veterinary officer, Uganda; J. Nicholls, livestock officer, Nyasaland; F. S. Peritz, veterinary officer, Local Civil Service, Gold Coast; J. F. Redhead, assistant conservator of forests, Nigeria; J. M. A. Sly, scientific officer (agronomist), Nigeria; S. R. Smithers, scientific officer, Gambia; H. A. W. Southon, scientific officer (entomologist), East Africa Tsetse and Trypanosomiasis Research and Reclamation Organization, East Africa High Commission; L. G. Stephens, veterinary officer, Hong Kong;

S. L. Wanrooy, tobacco-growing expert, British Honduras.

The Night Sky in April

NEW moon occurs on April 8d. 12h. 25m., U.T., and full moon on April 18d. 05h. 48m. The following conjunctions with the moon take place: April 1d. 18h., Mercury 7° S.; April 4d. 18h., Venus 6° S.; April 8d. 03h., Jupiter 3° S.; April 19d. 05h., Saturn 8° N.; April 23d. 17h., Mars 1° N. Mercury is too close to the sun for favourable observation during the month. Venus, an evening star, rises at 19h. 50m., 20h. 35m. and 21h. 20m. on April 1, 15 and 30, respectively, the stellar magnitude of the planet varying between 3.4 and 3.3 and the visible portion of the illuminated disk between 0.967 and 0.929. Mars rises at 1h. 15m., 0h. 50m. and 0h. 10m. at the beginning, middle and end of the month, respectively; its eastward movement during April carries it a little north of λ Sagittarii towards the end of the month, and its stellar magnitude varies from 0.1 to -0.6, the great increase in brightness being largely due to its approach to the earth, from 89 to 66 million miles during April. Jupiter sets at 0h. 50m., 0h. and 23h. 15m. on April 1, 15 and 30, respectively, its stellar magnitude varying from -1.7 to -1.6; its slow eastward movement from the west to the east of ζ Tauri can be easily seen during the month. Saturn rises at 20h. 50m., 19h. 50m. and 18h. 40m. on April 1, 15 and 30, respectively, and is easily recognized, stellar magnitude 0.4, a little east of $\times$ Virginis. Occultations of stars brighter than magnitude 6 are as follows, observations being assumed to be made at Greenwich: April 6d. 20h. 44.7 m., 36 Taur. (D); April 8d. 21h. 31.9 m., 5 Gemi. (D). D refers to disappearance. The Lyrid meteors, the debris of Comet 1861 I, are active during about April 20-23, but moonlight will interfere with their observation during the later part of the night.

Announcements

THE Council of the Linnean Society of London has nominated Prof. F. E. Fritsch, emeritus professor of botany in the University of London, for the award of the Linnean Gold Medal for 1954, and Prof. Irene Manion, professor of botany in the University of Leeds, for the Trail Award and Medal. The presentation will be made at the Anniversary Meeting on May 24.

THE Hinchley Medal of the British Association of Chemists has been awarded to Mr. George T. Gurr, an authority on stains for microscopical work and their manufacture and author of "Biological Staining Methods", who has been prominently connected with the Association for a number of years.

DR. A. R. J. P. URBELONDI, professor of chemistry in The Queen's University of Belfast, has been appointed to the University of London chair of thermodynamics tenable at the Imperial College of Science and Technology.

DR. B. P. DUDDING, vice-chairman of the Advisory Scientific Panel of the Research Laboratories of the General Electric Co., Ltd., has been made an "Ufficiale dell' Ordine al Merito della Repubblica Italiana", in recognition of his services to the Italian glass industry. Dr. Dudding has given long service to various bodies connected with glass and glass technology, both national and international, and was president

of the International Commission on Glass in July last year.

A FARADAY SOCIETY Discussion on "The Study of Fast Reactions" will be held during April 7-9 in the Department of Chemistry, University of Birmingham, under the chairmanship of the president of the Society, Prof. R. G. W. Norrish. The meeting will be in two parts, gas reactions and solution reactions, which will be given a general introduction by Prof. H. W. Melville (University of Birmingham) and Mr. R. P. Bell (University of Oxford), respectively. Further information can be obtained from the Secretary of the Society at 6 Gray's Inn Square, Gray's Inn, London, W.C.1.

THE Imperial College of Science and Technology will be holding a summer school in mineral dressing in the Bensham Laboratory, Royal School of Mines, Prince Consort Road, London, S.W.7 (see p. 585 of this issue), during September 14-17 (10 a.m.-5 p.m. each day). The course will include lectures covering comminution, classification, grinding control, gravity separation, flotation and ancillary processes and will be illustrated by films, demonstrations and class work. The fee for the course is £10 10s. Application forms can be obtained from the Registrar, Imperial College, Prince Consort Road, London, S.W.7.

THE conference on oxidation processes, arranged jointly by the Institution of Chemical Engineers, the Chemical Engineering Group of the Society of Chemical Industry, the Royal Institution of Engineers (Chemical Engineering Group) of the Netherlands and the Royal Netherlands Chemical Society (Section for Chemical Technology) (see *Nature*, February 6, p. 245), will not now be held in The Hague, as previously announced, but instead will be in Amsterdam during May 6-8 at the Royal Tropical Institute (Koninklijk Instituut voor de Tropen), Mauritskade 63.

THE Third General Assembly and International Congress of the International Union of Crystallography will be held in the Faculté des Sciences, 47 rue des Écoles, Paris 5^e, during July 21-23. Two symposia are being arranged to take place during the Congress: location and function of hydrogen, organized by Dr. W. Cochran, of the Cavendish Laboratory, Cambridge; and the mechanism of phase transitions in crystals, organized by Dr. W. G. Burgers, of the Technical Institute, 136 Julianalaan, Delft. Those intending to participate in either of these symposia should write before March 31 to the organizer and also to the secretary of the Congress, A. J. Rose, 1 rue Victor-Cousin, Paris 5^e, from whom all further information concerning the Congress can be obtained.

It is proposed to publish in the near future a new journal, to be entitled *Gwerin: an International Journal of Folk Life*, which will be devoted to papers, notes, reviews, etc., on all aspects of folk-life research in Great Britain and Ireland and their relations with the Continent of Europe (including Scandinavia). The language of the journal will be English. The general editor of the journal is Dr. Iorwerth C. Peate, curator of the Welsh Folk Museum, St. Fagans, near Cardiff. Two parts will be published each year, each being about sixty pages ($7\frac{1}{2} \times 9\frac{1}{2}$ in.), with plates, and costing 5s. 6d. post paid. All those wishing to subscribe to this new journal should write as soon as possible to Dr. Peate.

A NEW GYROSCOPIC INSTRUMENT

A NEW instrument known as the 'Gyrotron', which has been made by the Sperry-Gyroscopic Co., is an important step in aircraft instrumentation and is interesting in that it has been developed from observation of the flight-control methods of Diptera. J. W. S. Pringle was the first to give a fully satisfactory explanation of the mechanism and functions of the halteres of Diptera¹. These club-shaped lateral projections from the fly's thorax vibrate in a vertical plane through an angle of some 150° during horizontal flight, the motion having a constant amplitude and being maintained at the natural frequency of the system (Fig. 1). The large amplitude of this motion means that in the plan view the mass represented by the end knob of the haltere has a lateral in-and-out motion at twice the frequency of the oscillation of the haltere, since the knob moves inwards and outwards for the half-cycle while it is above the horizontal position, and again for the half-cycle while it is below this position. By reason of this in-and-out component of the motion, the fly is able to detect a yawing turn. If during flight the fly starts such a turn (about the vertical axis), forces, called Coriolis forces, are developed as a result of the combination of the turn with the motion described. These Coriolis forces also arise in gyroscopic apparatus and, as will be seen later, in the new type of 'vibratory gyro'.

The Diptera have sense organs at the base of the halteres which detect the action resulting from the Coriolis forces. These give a signal which enables the fly to correct the rotation and maintain a straight course—a task which experiment shows to be impossible for a fly from which the halteres have been removed.

Fig. 1. Diagram illustrating movement of halteres

Fig. 2. Plan of vibrating tuning fork

The engineers developing the 'Gyrotron' had to produce an instrument sensitive to a very much slower rate of yawing rotation than the fly's halteres, and their success is indicated by the fact that they are able to measure rotations as slow as that of the earth. This is done by a rugged instrument which has a range of speed indication up to about a hundred revolutions per minute.

The basic detector unit of the 'Gyrotron' consists essentially of a tuning fork which is maintained in vibration, with constant amplitude, by an electromagnetic drive. This is used to detect a rotation about the axis of the 'handle' of the fork (Fig. 2). The tines oscillate inwards and outwards in a way that corresponds to the essential part of the motion of the halteres of a fly. This leaves the problem of detecting

the Coriolis forces generated when the fork is rotated about its axis.

Another way of expressing the Coriolis effect is to say that, as the tines oscillate, the moment of inertia of the fork about the handle axis varies periodically with the frequency of the vibration of the fork, and may be expressed by $I = I_0 + I_1 \sin \omega t$, where $\omega = 2\pi n$ is the frequency, I_0 is the moment of inertia of the fork when the tines are in the mean position, and I_1 represents the greatest departure from this mean. If a rotation, with constant angular velocity Ω about the handle axis, is given to the fork, the angular momentum about the axis is given by

$$V = \Omega (I_0 + I_1 \sin \omega t).$$

In order to maintain this rotation, the couple applied to the handle of the fork must be

$$L = dV/dt = I_1 \Omega \omega \cos \omega t.$$

It is this alternating couple that the instrument engineer must detect and measure. It corresponds exactly to the requirements of the sense organs at the roots of the halteres, except that the sense organs observe each haltere independently, while in the 'Gyrotron' the tines of the fork always move in unison so that the effect on the fork as a whole may be observed.

The basis of detection is to support the fork on a torsional spring of such stiffness that its natural frequency on the spring is also n . The fork then develops an oscillatory torsional motion just as though the couple L were being applied to it directly, thereby making use of the large dynamic magnification of the resonant system. What is actually measured, by a suitable pick-up, is the velocity associated with the oscillatory rotation, which is superimposed on the steady applied rotation Ω . Provision is made for electromagnetic damping of the motion, this being necessary when measuring higher angular velocities. The velocity of the oscillatory rotation gives a measure of the angular velocity Ω , and its phase, relative to the time motion, indicates the direction of Ω . The output signals are suitably combined to give a direct reading of angular velocity on a dial. A considerable amount of electronic equipment is, of course, used; but the whole instrument, including amplifiers, although only in the early stages of development, weighs less than 7 lb.

The development of this device as a normal rate-of-turn meter for aircraft is clearly an immediate possibility. It is at once more robust and more sensitive than the gyroscopic type currently in use. Future developments lead towards a directionally stable instrument (like a free gyroscope) and perhaps to a complete replacement of gyroscopic instruments—even the gyro-compass—by 'Gyrotron' types; for once it is possible to detect rotation in this way, it should ultimately be possible to maintain it at any desired value.

POWER FROM ATOMIC ENERGY*

ONLY when concentrated sources of energy—or fuels—were discovered did modern civilization become possible. While complete mechanical use of their energy is possible in principle, this has not yet been accomplished even with chemical fuels, and only 30–40 per cent utilization of the irreversible heats of reaction is possible. Nuclear fuels, a million times more concentrated than chemical fuels, are now becoming practically useful, and thermonuclear reactions—at present used only explosively—may enter the field eventually.

Nuclear reactors cannot be very small and are probably impracticable for vehicles and aircraft—though very promising for ships. Their greatest importance—now that breeding is possible in fast reactors—will be as sources of large-scale power. The cost cannot be predicted realistically, but it might eventually come down to that of power from coal—which, in any event, represents only a few per cent of the cost of industrial products.

The practical difficulties of nuclear power production are immense. Materials have to withstand radiation and high temperatures. Operation of plant must be largely by remote control, and the large-scale disposal of fission products will be difficult. Very careful planning is necessary for safety and economy—because plants are necessarily large. The designers of the prototype submarine reactor—though 'firmly optimistic' about the future—have emphasized these problems, which will become still more acute in power breeders.

Countries have greatly differing needs for nuclear-power projects. The United States will clearly continue development—for prestige reasons and because it can now afford to export plant. Canada must be interested because of her undeveloped northern regions. The U.S.S.R., which can probably benefit more than the United States, will also be influenced by considerations of prestige. Many small European countries have entered the field—at the risk of absorbing too much of their technology. Africa and other undeveloped countries need nuclear power vitally.

In Great Britain nuclear power could augment coal power substantially and its prospects must be carefully examined. Allowing for, say, three generations of reactors during development and assuming an expenditure comparable to the present expenditure on new electrical generating plant, it would be approaching the end of the century before the present production of electricity from coal could be equalled. But by this date Britain ought to have increased power production about five times to compete industrially with the United States. Since only one-sixth of her coal is used to produce electricity in Britain, there is clearly no prospect of substantially reducing the consumption of coal, and a much greater effort should be devoted to fuel-saving.

At the same time, Britain has a unique opportunity of regaining her economic balance by exporting nuclear power plant to other countries. Such a project would require full industrial participation and a real national effort to increase scientific manpower and use of science, and to reduce waste.

* Summary of a lecture by Prof. F. H. Simon, O.B.E., F.R.S., being the third of the series of public lectures arranged by the Atomic Scientists' Association and the Department of Extra-Mural Studies of the University of London (see also *Nature* of February 27, p. 286, and March 13, p. 477).

Among British assets are brain-power and freedom from the crippling 'spy-hunt' atmosphere, and atomic energy could have a decisive influence on Britain's future. But those who think this will come without effort are mistaken.

GROUND-WAVE PROPAGATION AT ULTRA-HIGH FREQUENCIES

THE general trend of development of television and other radio services to increasingly higher frequencies emphasizes the need for more detailed knowledge of the characteristics of wave propagation over the ground at such frequencies. Two papers of interest in this connexion were read before the Radio Section of the Institution of Electrical Engineers on February 10.

The first paper, by Dr. J. A. Saxton and B. N. Harden, described the results of an experimental investigation of the effects of irregular terrain on ground-wave propagation at frequencies of 102.6 and 593.6 Mc/s. Particular attention was paid to the work at the higher frequency, which is midway between the bands, known as IV (470–585 Mc/s.) and V (610–960 Mc/s.), allocated for the future development of television in Great Britain.

With the aid of an experimental transmitter set up first at the Radio Research Station, Slough, on a mast 28 m. high and 40 m. above sea-level, and later at the B.B.C. station at Sutton Coldfield, from a mast at a height of 184 m. above ground and 365 m. above sea-level, measurements of received field strength were made in various directions out to distances of nearly 100 km. Within this range, variations of field strength arising from changes in atmospheric refraction sometimes occur, but they are of little significance compared with the effects of the terrain, which result in relatively large changes in strength for different directions of transmission or for small displacements in the actual location of the receiver. Having in mind the irregular nature of the ground over which the propagation must be studied, the results of the variation of field strength with distance must be presented on a statistical basis. Thus it was found that at the lower of the two frequencies used (near 100 Mc/s.) the relation between median field strength and distance agreed fairly closely with the theoretical values calculated for transmission over a smooth earth. At the higher frequency (near 600 Mc/s.), however, it was found that the median field strength at a distance of 70–80 km. may be as much as 20 db. below that estimated for smooth-earth conditions. Moreover, it was found that, with a receiving aerial at the usual height of about 9 m., considerable further attenuation may be experienced in heavily built-up areas. A fairly wide range of variation of field strength may also occur over a small range at any particular receiving site, in extreme cases amounting to 20–25 db. This experience indicates that considerable care may be needed in the choice of position of a receiving aerial when television transmission takes place at wave-lengths corresponding to one or two feet.

In the second paper, Dr. J. A. Saxton has collected information of the type described above, together with the results of similar investigations conducted in the United States, so as to compare the experi-

mental data for ground-wave propagation at frequencies between 50 and 800 Mc./s. with the corresponding conditions for transmission over a smooth earth. The graphs accompanying the paper show that, whereas for given transmitter conditions the field strength at a given distance over a smooth earth increases with the frequency, this effect is more than counterbalanced by the effect of the irregular terrain under conditions realized in practice. Thus, at the lower end of the frequency band (50–70 Mc./s.) there is little difference between median field strengths observed over irregular terrain and those calculated on the assumption that the earth is smooth. As the frequency is increased above 70 Mc./s., the observed median field strength falls more and more below the ideal theoretical values, the difference being as much as 20 db. at 700 Mc./s. The experimental work thus makes it possible to provide a simple empirical modification to the ideal smooth-earth propagation characteristics which will give the median field strengths to be expected over irregular terrain.

The discussion which followed the presentation of these papers showed that the conclusions are of considerable interest and importance to those who will be responsible for the development of future television and communication services at these higher radio frequencies.

SCIENTIFIC APPRAISAL OF SINGING VOICES

By DR. FRITZ WINCKEL

Institut für Schwingungsforschung, Technische Universität, Berlin-Charlottenburg

WHILE it has long been possible to describe exactly the 'spectrum' of voices in speech, no detailed knowledge has hitherto been available about the spectrum of the trained singing voice, especially the timbre. In earlier investigations, the physical conditions were not exactly defined¹, and in particular the analyses made from normal records led to doubtful conclusions². We have tested a considerable number of voices of well-known singers by electro-acoustic means, in order to obtain a better knowledge of the physical properties of trained singing voices. If, say, a singer is singing in a medium pitch of about 300 c./s. in mezzo-forte, about ten partial tones are present. Each of these can be co-ordinated with a particular vowel quality and have a greater or less share in the full sound, depending upon the type of text, the pitch and the quality of the singing voice. By analogy with optics, these partial tones can be termed 'vowel colour' (*Vokalfarbe*). Thus the timbre of a trained singing voice can be distinguished from the 'flat' voice of an untrained singer by the fact that all vowel colours are available simultaneously in a certain modulation of intensity. Physically, the character of a good singing voice consists of the most favourable mixture of these vowel colours forming a 'complex colour' (*Komplexfarbe*). There are other features of importance; for example, a nasalizing region around about 2,000 c./s. (the so-called *Nasalformant*) and a carrying region of about 3,000 c./s., which is thought to correspond to the active radius of the singing voice. In addition, there are other frequency regions which can be defined as 'metallic', 'hollow', 'sharp', etc.³.

In a studio which is damped to the utmost, singers have a more pithy voice than in a resounding hall. This is explained by the fact that in a damped studio the trained functions are more active, since unfavourable auto-suggestive influences through the ear and the central nervous system of the singer are avoided.

When testing singers' voices, the 'dynamic volume' has been measured by means of sound energy meters and an individual sound energy-level determined, a factor which has hitherto been overlooked by other investigators, leading to questionable results.

Deviations from the characteristic frequency properties of the singing voice indicate vocal disease or affections of the respiration organs. In co-operation with physicians a practical diagnostic method by analysis of microphone recordings has been worked out for application by ear, nose and throat specialists.

As a result of these investigations, the Technical University of Berlin-Charlottenburg has established a centre for voice estimation and training, to serve the purposes of teachers of singing and physicians. Magnetophone recordings of voices can be sent in for analysis; and the singer or patient receives a sound spectrum with an explanatory note. Such analyses have the documentary value of an X-ray photograph or electro-cardiogram.

A special instrument, called a 'repeater' (*Repeatergerät*), has been developed by the Institute of Wave Research for the analysis of singing voices. The singer needs only to sing notes of short duration, which are lengthened by the repeater to continuous notes for analysis. Another important use of the repeater is in teaching. In the course of a considerable period of experiment, the Institute has tested in particular coloratura voices, by means of continual repetition of particular passages of the recording, for the qualities of 'attack', intonation, etc. This 'listening-in' to extracts of note sequences has often helped a student of singing to achieve a remarkable improvement in performance.

SCIENCE AND MODERN COSMOLOGY

PROF. H. DINGLE delivered on February 18, 1953, his retiring presidential address to the Royal Astronomical Society, selecting "Science and Cosmology" as his subject, and the full text has now been published (*Mon. Not. Roy. Astro. Soc.*, **113**, 3; 1953). Prof. Dingle pointed out that in the earlier stages of science the world was so full of mysterious phenomena that there was no temptation to go outside experience in search of other realms; in addition, it became almost an intuition with scientists that at every stage they must submit their findings to the test of observation. While science then incurred little danger of violating its own principles, unfortunately this state of affairs does not always exist to-day, and in the realm of cosmology it has almost completely disappeared. The universe is no longer the observable world that was once the sole

Electrothermal Rubber Sheetting speeds up
setting of adhesives, bonding, lamination

ELECTROTHERMAL RUBBER SHEETING is causing a revolution wherever quick setting of adhesives is called for. Safe, durable, completely flexible, **Electrothermal Rubber Sheetting (E.R.S.)** can be applied to practically any shape. E.R.S. is available insulated with Natural Rubber, P.V.C. Neoprene, Silicone Rubber, etc., and can supply controlled heat up to 350° C. The furniture industry, for instance, is using E.R.S. to eliminate gluing bottlenecks. It can be used to speed up setting of shapes, doors, cabinets, veneers, laminations . . . adhesives in aircraft construction and ship-building. E.R.S. also functions efficiently for flat pad and strip-panel heating. Available in widths up to 6 feet, and in any length you specify. If you have any localised heating problem, whatever the nature, write or phone now to **Electrothermal Engineering Limited, 270** *****

- AHLFORS, L. V., BERGMAN, S., BERS, L., BOCHNER, S., CALABI, E., FOURES, L., HEINS, M., JENKINS, J. A., KAKUTANI, S., KAPLAN, W., KODAIRA, K., MORSE, M., NEHARI, Z., ROSENBLUM, P. C., ROYDEN, H. L., SARIO, L., SCHAEFFER, A. C., SCHIFFER, M., SHIFFMAN, M., SPENCER, D. C., and WARSCHAWSKI, S. E. Contributions to the Theory of Riemann Surfaces: Centennial Celebration of Riemann's Dissertation. (Annals of Mathematics Studies No. 30.) Super Royal 8vo. Pp. vii+264. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1953.) 25s. net.*
- HOUSEHOLDER, ALAN S. Principles of Numerical Analysis. (International Series in Pure and Applied Mathematics.) Med. 8vo. Pp. x+274. (London: McGraw-Hill Publishing Company, Ltd., 1953.) 48s.*
- MACLACHLAN, N. W. Complex Variable Theory and Transform Calculus, with Technical Applications. Second edition. Demy 8vo. Pp. xii+388. (Cambridge: At the University Press, 1953.) 55s. net.
- MUSKHELISHVILI, N. I. Singular Integral Equations: Boundary Problems of Function Theory and Their Application to Mathematical Physics. (Second edition, Moscow 1946.) Demy 8vo. Pp. viii+448. (Groningen: P. Noordhoff, N.V., 1953.) 28.50 florins.*
- ROMIG, HARRY G. 50-100 Binomial Tables. Fcap. 4to. Pp. xxvii+172. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953.) 32s. net.*
- SIGHT REDUCTION TABLES FOR AIR NAVIGATION. Vol. 3: Latitudes 40°-89°, Destinations 0°-29°. (A.P.3270.) Royal 4to. Pp. x+339. (London: H.M. Stationery Office, 1953.) 21s. net.*
- TARSKI, ALFRED, in collaboration with MOSTOWSKI, Andrzej, and ROBINSON, RAUFEL M. Undecidable Theories. (Studies in Logic and the Foundations of Mathematics.) Demy 8vo. Pp. xi+98. (Amsterdam: North-Holland Publishing Company, 1953.) 9 florins; 18s.; 2.50 dollars.*

Physics

- BAK, Borge. Elementary Introduction to Molecular Spectra. Ex. Cr. 8vo. Pp. x+126. (Amsterdam: North-Holland Publishing Company; New York: Interscience Publishers, Inc., 1954.) 9 florins; 18s.*
- BECKERLEY, JAMES G. (edited by). Annual Review of Nuclear Science. Vol. 3, 1953. Med. 8vo. Pp. x+412. (Stanford, Calif.: Annual Reviews Inc., in co-operation with The National Research Council of the National Academy of Sciences, 1953.) 7 dollars.*
- BRITISH JOURNAL OF APPLIED PHYSICS. Supplement No. 2: Static Electrification. (A symposium held by The Institute of Physics in London on 25, 26 and 27 March, 1953.) La. Post 4to. Pp. iv+104+iv. (London: Institute of Physics, 1953.) 25s.*
- BULLEN, K. E. An Introduction to the Theory of Seismology. Second edition. Demy 8vo. Pp. xv+296. (Cambridge: At the University Press, 1953.) 35s. net.*
- DRAYCOTT, L. T. Elementary Practical Physics. Cr. 4to. Pp. 152. (London: Edward Arnold and Co., Ltd., 1954.) 7s. 6d.
- FRISCH, O. R. (edited by). Progress in Nuclear Physics, Vol. 3. (Progress Series.) Royal 8vo. Pp. vii+279+4 plates. (London: Pergamon Press, Ltd., 1953.) 63s. net.*

POWER, Sir D'Arcy (the late), LE FANU, W. R. (continued by). *Lives of the Fellows of the Royal College of Surgeons of England 1930-1951*. Royal 8vo. Pp. xli+890. (London: Royal College of Surgeons of England, 1953.) 42s.*

SCIENTIFIC AMERICAN READER. Mod. 8vo. Pp. xxv+626. (New York: Simon and Schuster, 1953.) 6 dollars.*

THE YEAR THAT MADE THE DAY: How the B.B.C. Planned and Prepared the Coronation Day Broadcasts. Ls. Fcap. 4to. Pp. 80. (London: British Broadcasting Corporation, 1953.) 6s.*

UNDERWOOD, E. Ashworth (collected and edited by). *Science, Medicine and History: Essays on the Evolution of Scientific Thought and Medical Practice, written in honour of Charles Singer*. Vol. 1: Pp. xxviii+563+50 plates. Vol. 2: Pp. viii+646+56 plates. Super Royal 8vo. (London: Oxford University Press, 1953.) 2 volumes £11 11s. net.*

Scintillators

CRYSTALLINE AND PLASTIC PHOSPHORS
FOR ALPHA, BETA, GAMMA, X-RAYS AND NEUTRON MEASUREMENTS

Also available

- ZINC SULPHIDE POWDER
- ZINC SULPHIDE IN PERSPEX
- CADMIUM SULPHIDE CRYSTALS

• We are exhibiting
in the Physical
Society Exhibition
Imperial College, London
8th-17th April, 1954

SODIUM IODIDE—Supplied in a sealed, ready to use capsule.

PLASTIC—The extreme purity of the manufacture of this Tetraphenyl Butadiene ensures good response. It is economical, has excellent optical characteristics and is simple to handle and use. Available in large sections—in bulk, or machined to requirements.

Details of these Scintillators together with specifications of the Isotope Scintillation Counter Head and nucleonic equipment available on request.

object of astronomical study; on the contrary, it is, he said, "a hypothetical entity of which what we can observe is an almost negligible part". Assertions now made about it require observations over the remote past or over millions of years in the future, if they are susceptible of test at all, and hence speculation is inevitable; only strict adherence to the essential principles of science can control such speculations, and in cosmological studies a knowledge of the history and philosophy of science is most essential.

Prof. Dingle commented on a number of recent speculations by some cosmologists. Thus it has been stated that it is against the spirit of scientific inquiry to regard observable effects as arising from causes unknown to science, and that in principle this is what creation-in-the-past implies. Prof. Dingle said that confession of ignorance, far from being unscientific, is a characteristic of the scientific attitude, in support of which quotations are available from the works of Galileo and Newton. Perhaps the most extraordinary thing about the second statement, he continued, is that this idea of the creation of matter is just that which is opposed to the spirit of scientific inquiry—that the observable universe was created in the past by causes unknown to science.

Another statement claimed by Prof. Dingle to be fallacious is connected with an underlying assumption in experimental science; this assumption is that the repetition of an experiment will reproduce the original results. But experimental science is not based on an assumption; "it is an adventure in which you accept whatever you find, and although you may be guided in a particular case by an expectation, the experiment may reveal something totally different". An instance of this is found in the case of Schwabe, who counted sunspots with the object of finding an intra-Mercurial planet, and instead of doing so he found the eleven-year solar period. But if he had counted the spots with any other object or no object at all, he would still have found the eleven-year solar period; it would be futile to believe that the achievements of experimental science would necessarily lose all significance if it were discovered that some assumption proved baseless. In the realm of psychology it is accepted that no experiment when repeated produces the original result, and even in physics it has been held for a long time that no experiment is repeatable, the entropy of the universe never being twice the same.

A very severe criticism of 'the cosmological principle' and 'the perfect cosmological principle' advocated quite recently in some quarters was the next topic in Prof. Dingle's address. The evidence for these, he said, is practically non-existent, and he advocated a principle which, he thinks, will command universal assent: "No statement about the universe, or nature, or experience, or whatever term you prefer for the object of scientific investigation, shall be made . . . for which there is no evidence". At present we are faced with the rather disconcerting fact that any statement can be made about the universe if it cannot immediately be refuted; and if anyone is attracted by an idea for which there is no evidence, it is only necessary to call it a 'principle', no evidence being then required. When we are informed that matter is being continually created, but in such a way that the process is imperceptible, obviously the statement cannot be disproved; but

when we ask why it should be accepted, we are informed that the fundamental axiom of science requires it. To avoid using names which he considers misleading, Prof. Dingle referred to the 'cosmological principle' as the "cosmological assumption" and to the 'perfect cosmological principle' as the "cosmological presumption".

Holding, as he does, that the object of scientific investigation is the world of experience or even experience itself, and that all advances in science consist either in enlarging the range of experience or in expressing the regularities found or to be found in it, Prof. Dingle has no place for the new doctrine that experience must conform to the tastes of the investigator. Equally he completely rejects its twin doctrine that experience must conform to a pattern which we can deduce by pure reason. The usual form of this latter doctrine is that the laws of Nature can be derived by reason without recourse to experience, but those who hold this view overlook the important fact that, by definition, laws of Nature are laws followed by what we experience and not by what we deduce from our axioms. A remarkable position in cosmology, he said, is that two impostors have usurped the throne of science, one of which is personal taste and the other is pure reason, and although they are not new, one of them—personal taste—has never before presented itself so brazenly. The reasons given by Prof. Dingle for this revival are traced to the theory of relativity—a very remarkable thing when we remember that the very essence of that theory lay in the recall of science to experience. The solution of certain problems of classical physics lay in the fact that some concepts had been assumed to be directly related to experience, but the assumption was incorrect. For example, it was proved that by no physical process is it possible to determine unambiguously the absolute simultaneity of separated events. Hence, to establish science on its proper basis—that of experience—such concepts were eliminated, and experience was described "in terms of those concepts alone which had a precise empirical meaning"; the error which was corrected arose from incomplete consideration of the effects of changing the co-ordinate system. This subject is fully dealt with in Prof. Dingle's address.

Towards the end of the address the attention of the new cosmologists was directed to biology, in which a problem somewhat similar to that confronting cosmologists arises: "We observe living matter and dead matter, but we never experience the creation of living matter out of dead matter alone". It may be assumed that in the past dead matter became alive by an unknown process, or we may suppose that the process has been going on eternally but at an undetectable rate. The first alternative is "against the spirit of scientific inquiry" according to the modern cosmologist, who presumably will be forced to postulate the continual animation of matter—a view which Prof. Dingle believes is ruled out by the cosmologists' own scheme. If the matter of which the earth is composed was created as separate atoms, it could not have begun to live for many millions of years, and hence terrestrial life must have begun at some particular epoch. To escape from the dilemma, the cosmologist must deny the existence of living matter—a most improbable attitude—or he must violate "the spirit of scientific enquiry".

Prof. Dingle concluded: "And so, when it happens that we have published, in the name of science, so-called 'principles' that, in origin and

character, are identical with the 'principles' that all celestial movements are circular and all celestial bodies immutable, it becomes my duty to point out that this is precisely the kind of celebration that science was created to displace. . . . In cosmology we are again, like the philosophers of the Middle Ages, facing a world almost entirely unknown".

NATIONAL RESEARCH DEVELOPMENT CORPORATION: CONTINUATION OF BORROWING POWERS

THE Development of Inventions Bill, as foreshadowed in the fourth annual report of the National Research Development Corporation (see *Nature*, February 6, p. 249), received its second reading in the House of Commons on January 26. The Corporation's borrowing powers under the 1948 Act expire on June 30, 1954, and the Bill extends from five to ten years the period during which advances may be made to the Corporation and payment of interest on such advances waived. Numerous tributes to the work of the Corporation were paid during the debate, and in moving the second reading of the Bill, the President of the Board of Trade, Mr. P. Thorneycroft, explained the purposes of the clause which slightly extends the scope of the Corporation's activities. There appeared to be some doubt as to whether under the original Act the Corporation was empowered to carry out research for the purpose of developing an existing invention if this should lead to a substantially new invention. The first sub-section of Clause 2 of the new Bill is intended to remove this doubt and authorizes the Corporation to promote or assist any research likely to further the development or exploitation of inventions or to enhance their value.

The second sub-section of this same clause, Mr. Thorneycroft explained, arose from a comment in the last report of the Advisory Council on Scientific Policy as to the desirability of extending the existing organization for the use of research and development contracts. The sub-section authorizes the Corporation to promote and assist research intended to satisfy specific practical requirements where the Corporation believes the research is likely to lead to an invention, while a further sub-section of the clause empowers the Corporation to assist the continuation of a research which hitherto has proved fruitless from a practical point of view but which appears likely to lead to practical results. Exercise of its functions under these two sub-sections is subject to the approval of the Lord President of the Council and of the President of the Board of Trade.

Mr. Thorneycroft explained that this proviso was introduced to avoid the overlapping of the work of the Corporation and that of the universities, of other government departments or of research organizations like the Medical Research Council or the Department of Scientific and Industrial Research. He also stressed the point that the Corporation's task is to promote and assist research. It is not primarily to undertake research, he said, and is never to undertake it in competition with industry or with other government departments. When the Bill received its third reading on February 1, the Parliamentary Secretary

to the Board of Trade added further that it was never intended to give the Corporation general powers to undertake surveys or investigations to discover the practical needs of industry. That, he said, can best be done by industry itself, though possibly with the help and encouragement of government departments and at the suggestion of the National Research Development Corporation. Once such an investigation has established the prospect of industrial benefit, the powers to be given to the Corporation will enable it to take the responsibility for getting the required research done.

Two comments which were made during the debate on the second reading of the Bill are of particular interest. Mr. John Edwards, in welcoming the Bill, pointed out that the National Research Development Corporation is now inevitably involved in the provision, in a modest way, of risk capital, and he thought that the Bill would enable the Corporation to make a further contribution towards restoring a balance between the proportion of the resources devoted to fundamental research and those devoted to development. Mr. Austen Albu, who estimated the total expenditure during 1951 in Britain on research and development to be £268 million, of which £70 million was for civilian research, stressed the need to stimulate backward industries and to avoid overlapping. In some research associations, he said, there is a belief that projects in their field are sometimes undertaken in government establishments; and Mr. H. Strauss assured him that the reference to the President of the Board of Trade and the Lord President of the Council was designed simply to prevent such overlapping.

COMMONWEALTH FUND, NEW YORK

REPORT FOR THE YEAR 1952-53

THE thirty-fifth annual report of the Commonwealth Fund* covers the year ending June 30, 1953, and deals primarily with the activities for which grants were made during 1952-53. For medical education appropriations during the year totalled 602,977 dollars, for experimental health services and hospital activities 224,323 dollars, for medical research 517,101 dollars, for advanced fellowships in medicine and allied fields 75,000 dollars, for the Division of Education 310,050 dollars, and a special grant of 2,750,000 dollars was made for the construction of a dormitory, to be known as the Edward S. Harkness Memorial Hall, for medical students at Yale University. Actual disbursements during the year from current and previous appropriations totalled 2,584,179 dollars. Among the nine projects in medical education for which new or renewed appropriations were voted are a programme at Cornell University Medical College to provide students with a wider experience in medical care through continuity of contact with patients; grants to the University of Pennsylvania School of Medicine for the continuance of its family adviser programme until it is fully incorporated in the University framework, and for a year's pilot-study of the medical school as an educational environ-

* The Commonwealth Fund. Thirty-Fifth Annual Report for the Year ending June 30, 1953. Pp. x+28. (New York: Commonwealth Fund, 1953.)

ment; a revised teaching programme at the Medical School of Western Reserve University, in which a systematic effort is being made to correlate basic science subjects with clinical ones; and further support to the study of psychiatry and its relation to medicine at Washington University, the University of Louisville and the Saskatchewan Department of Public Health.

The Fund continued its support of the major experiment in integrated health care in Hunterdon County, New Jersey, where a medical centre that was opened in June 1953 is testing the theories of its long-term planning. A further grant to Hunterdon was for a county-wide health inventory, and a grant was made to the Rip Van Winkle Foundation towards the development over three years of a mental health programme for Columbia County. Another grant went to the National Opinion Research Centre in Chicago for the completion of its national survey of opinion about mental health and illness, and support was also given to the qualitative study at the Yale Psychiatric Clinic of the effect of interactions between patients and staff and between the different ranks of staff on the daily life and therapeutic effectiveness of a psychiatric ward.

During the year the Fund reviewed its interests in the field of medical research to which over seven years it has given nearly three million dollars for fifty-seven projects. Projects for which support was discontinued were largely in the fields of infectious disease, cardiovascular disease and cancer research, where major support is now received from other sources. Current research grants cover nine projects, one of which was new in 1952-53, and are in three categories: the first, which is primarily concerned with interaction between organism and environment, includes studies of growth and personality development, certain types of neuro-psychiatric research and studies of relations between social environment and chronic disease; the second deals primarily with integrative processes within the organism and includes studies of the neurological and endocrine systems and their relations; and the third is weighted in favour of basic biological studies.

Advanced fellowships awarded during the year included four in medicine or surgery, one for advanced work in psychiatry, and five for interdisciplinary studies as well as two fellowships to foreign workers. The programme of fellowships offered to British graduates, journalists and Civil servants for study and travel in the United States was broadened in 1952 to include persons on the Continent of Europe by a series of awards for candidates from the Salzburg Seminar in American Studies. Forty-nine Fellows in all categories were in residence in the United States during the year beginning September 1952, including nine British Fellows of the 1951 class who were granted extensions. For the present year, fifty-nine Fellows will be in residence, including thirty-seven on new awards and seventeen on extensions, the two-year figures including sixteen 'Salzburg' Fellowships. For the latter the Fund has been experimenting with a new plan of selection in which it has been possible to make nominations after a month's daily experience with the participants. Experience over the years is heavily in favour of the tenure of at least one full year, including two or three months of travel in the United States, and stress is laid on the value of the fellowships in developing leadership, and also in encouraging the exchange of ideas and information.

DEFENCE STANDARDS LABORATORIES, AUSTRALIA

REPORT FOR THE YEAR 1952-53

SINCE the transfer to other sections of the Research and Development Branch of the Department of Supply, Commonwealth of Australia, of research and development work on new weapons, the Defence Standards Laboratories, which have now been incorporated in the Research and Development Branch, have concentrated on scientific advisory service, and the Chief Superintendent's annual report* for the year ended June 30, 1953, indicates the new functions and scope of the Laboratory. Broadly, they are the application of scientific knowledge and research in chemistry, physics, metallurgy and engineering to problems arising in design, development, manufacture, inspection, storage and use of defence material. They include the provision of a scientific advisory service and the research required to provide a sound basis for such service. Its standardizing work is based on sub-standards verified in terms of the national standards held by the National Standards Laboratory, Sydney, and the staff also participate in specification drafting work of the Standards Association of Australia. The testing work involves the use of an extensive range of measuring instruments of proved accuracy.

Among investigations to which reference is made in the present report are detailed studies of the direct production of polymeric butyl titanate on a pilot-plant scale, giving yields of more than 80 per cent. Pigmentation of this polymer with zinc dust gives a paint with outstanding anti-corrosive properties, particularly under marine conditions, and anti-fouling paints based on such polymers pigmented with copper oxide and mercuric oxide are also being developed. Further progress has been made in the study of indigenous drying oils, and five new paint-exposure sites were brought into use during the year. Oxidation tests and the oxidizing characteristics of mineral oils are being studied with the view of establishing tests for identifying the type of an oil, and studies are being made of type and degree of damage in flax, jute and sisal fibres due to fungal and other agencies. The ebullioscope method of determining the molecular weights of polymers has been used extensively in the preparation of polymers of butyl titanate and styrene, and some experience was gained in the preparation of cellular (foamed) plastics.

In metallurgical chemistry a rapid test was developed for detecting porosity in nickel coatings on zinc-base die coatings, and much work was done on anodic passivation phenomena encountered in the anodic etching of low-alloy steel in dilute sulphuric acid. Chromate has proved to be a satisfactory inhibitor of corrosion in a spray-tower heat-exchanger circuit, and work was completed on some aspects of the mechanism of corrosion inhibition on mild steel in dilute sulphuric acid solution when very small amounts of organic inhibitors are added. A modified procedure was developed for determining phosphorus in all classes of iron and steel. In crystal physics more attention is now being given to long-

* Research and Development Branch of the Department of Supply, Commonwealth of Australia. Annual Report of the Defence Standards Laboratories for the Year ended 30th June, 1953. Pp. 54. (Melbourn, Vic., Alexandria, N.S.W., and Finsbury, S.A.: Research and Development Branch, Department of Supply, 1953.)

range research, particularly the application of X-ray diffraction in metal physics, including the influence of prior deformation on the structural changes associated with the creep of high-purity aluminium, and a detailed study of the structural changes during the tertiary creep stage in this metal. A complete structure analysis has been made of the fibrous silicate, amosite.

The Electricity Group has developed a microwave spectrograph for analysing the molecular structure of gases and has continued investigations on the scattering of electrons from solids, where the electrostatic analyser holds most promise of success in measuring the energy distribution. In optics the Zernike phase-contrast test, the Johnson-Scholes interferometer and the Bates sheared-wave interferometer have been added to existing techniques for testing optical surfaces, while an experimental Schmidt-Cassegrain objective, 50 in. in focal length, is being developed. The technique of making metal bolometers of small time-constant to function as infra-red receivers has been developed further, while in physical metallurgy investigations into the behaviour of metals in service have included studies of inter-crystalline corrosion in aluminium alloys. In welding metallurgy, much useful information on brittle failure, strain ageing, quench ageing and residual welding stresses has been accumulated.

An investigation is now being undertaken into variation of pore-size, specific surfaces and general adsorption capacity of a series of sulphur-impregnated activated charcoals.

Details of the work of the New South Wales and the South Australia branches are included, and lists of publications and lectures, of committees and of senior and professional staff at June 30, 1953, are appended.

ENERGY TRANSFER IN MACROMOLECULES EXPOSED TO IONIZING RADIATIONS

By DR. P. ALEXANDER

Chester Beatty Research Institute, Royal Cancer Hospital,
London, S.W.3; and the Chemistry Department, Imperial
College, London, S.W.7

and DR. A. CHARLESBY

Atomic Energy Research Establishment, Harwell, Berkshire

IN gases there is abundant evidence¹ that the energy absorbed from ionizing radiations by one molecule can appear in another by transference of charge and excitational energy. In aqueous solution the energy absorbed by the water causes a change in the solute; since this process is now known to be brought about through the intervention of free radicals, the general term of energy transfer need not now be applied to these reactions². Recently, Manion and Burton³ found that the decomposition of cyclohexane was decreased in the presence of benzene, which presumably took up the energy from the excited or ionized cyclohexane molecule before this had dissociated. In all these cases collision between the molecules concerned is possible and, though there is no difficulty in principle, there is only limited evidence⁴ that energy from ionizing radiations

can be transferred within solids when the molecules are relatively immobile. A related effect is the transfer of energy within the same macromolecule from one part to another. Svedberg and Broholt⁵ observed that the giant molecule haemocyanin is split into identical parts by the traverse of a single α -particle, although the density of ionization makes it extremely unlikely that a single ionization can occur at a given site. This highly specific behaviour can be understood if energy absorbed anywhere within the giant molecule is mobile and able to break the bonds which hold the sub-units together. The smaller proteins which have been examined do not react in this manner but are degraded at random by α -particles to give a heterogeneous product. The following experiments with synthetic polymers provide direct evidence for energy transfer in saturated macromolecules of different constitution.

Polymethylmethacrylate is degraded at random by γ - and pile-irradiation, and from the simple function relating molecular weight with radiation dose it could be computed that one main-chain bond was broken for every 81 eV. energy absorbed⁶. This energy is not used only for main-chain breakdown but also includes associated reactions, such as decomposition of the ester side-chain, which occur simultaneously. When films of polymer containing 10 per cent of allylthiourea, aniline or *dimeta*-tolyl-thiourea were irradiated, 143, 152 and 227 eV. respectively had to be taken up by the system before a main-chain bond was ruptured. This protective effect, occurring in a system where the action of the radiation is 'direct', is now being studied in detail by Mr. D. Toms, whose preliminary experiments indicate that over a wide range protection is approximately independent of dose and proportional to the concentration of the added substance. The amount of radiochemical change which the latter undergoes is greater in the presence of the polymer than when it is irradiated alone. It seems likely, therefore, that the protection of the polymer is the result of energy transfer to the added substance. Since the area of the polymer molecules which is in physical contact with the additives can only be small, energy absorbed by ionization or excitation must be distributed over comparatively long distances before it can be taken up by the protective agent.

Polyisobutylene, like polymethylmethacrylate, is degraded by γ - and pile-irradiation, and from changes in molecular weight a value of 17 eV. was obtained for the energy absorbed per break in the main chain⁷. A co-polymer of 20 per cent styrene and 80 per cent isobutylene (kindly provided by Dr. Butler, of the Polymer Corporation, Canada) is more resistant than the pure isobutylene, and the energy required to break a main chain is increased approximately twice to 32 eV. The protection in this case can be interpreted as energy transfer from the isobutylene part of the chain to the aromatic ring system of the styrene, in which the energy is dissipated with only a very small amount of chemical change⁸.

In a similar way, the dose required to render a straight-chain hydrocarbon infusible (that is, to cross-link it to give an infinite network) is greatly increased by the presence of an aromatic ring. Cross-linking is the predominant reaction⁹ when straight-chain hydrocarbons are irradiated, and there is little, if any, chain breakdown. Although the energy required to produce a cross-link (c. 20 eV.) is independent of chain-length, the dose needed to render a

DOSE IN PILE UNITS* REQUIRED TO RENDER SUBSTITUTED DODECANES INFUSIBLE

Substituent	1-dodecane	4-dodecane	6-dodecane
1' naphthyl	48	—	—
2' naphthyl	48	62	66
2' decyl	—	—	37

* The pile unit is defined as a flux of 10^{17} slow neutrons/cm.² plus the associated γ -rays and fast neutrons. Comparison of cross-linking and degradation produced in the pile and by γ -rays from a cobalt unit indicates that one unit is equivalent to 4.5×10^4 r. for these reactions.

The compounds were kindly provided by Dr B. Bannar, of the Dyson Permas Laboratory, Oxford.

hydrocarbon infusible varies inversely as the molecular weight, since an average of one cross-link per molecule (weight average) is required for this change to occur. To render dodecane infusible, 27 units of pile-irradiation are required.

The addition of the saturated polycyclic hydrocarbon decalin at the centre of the paraffin molecule increases the dose slightly, whereas the presence of the aromatic naphthalene ring may render the straight chain much more difficult to cross-link, although any steric factors which could influence the reaction will be very similar in the two cases.

Since the amount of energy absorbed by the paraffin chain is not altered by the addition of other groups, we must conclude that the energy has been transferred to the aromatic ring before it could bring about the chemical changes leading to cross-linking. The table shows that maximum protection occurs when the aromatic ring is at the centre of the paraffin chain, and that the effect is smallest at the end. This suggests that energy transfer can occur along a saturated chain of twelve carbon atoms, but that it is more effective over shorter distances. The data indicate that the saturated ring exerts a small protective effect and that it contributes nothing to the cross-linking, since the corresponding C_{12} straight-chain paraffin, because of its higher molecular weight, required only 12.3 units to be rendered infusible.

The occurrence of energy-transfer processes in organic macromolecules may play an important part in the biological actions of ionizing radiations, since, as we have shown here, such transfers can result both in a decrease of total reaction by concentrating the energy in a group resistant to radiation, or by the preferential decomposition of a particular component. For example, the possibility can now be envisaged of protecting against a 'direct effect', since macromolecules need not decompose immediately on becoming ionized and can transfer their energy without undergoing reaction if a suitable receptor is present. Consequently, it cannot be concluded that any effect against which protection can be achieved by the addition of chemicals must invariably be the result of reactions with free radicals produced in the surrounding medium.

For the smaller viruses, Lee¹⁰ had found that an ionization anywhere within the organism leads to inactivation. The conclusion that every part of the virus was equally vulnerable is in contradiction to biochemical experiments, which had shown that many groups of the macromolecule could be modified without loss of activity. The results reported here indicate that the difficulty may be resolved if the target represents the distance over which energy transfer can take place, whereas the sensitive region

is smaller. If this view is accepted, 'direct' and 'indirect' are not fundamentally different, but represent merely two different mechanisms by which energy provided by ionizing radiations to the system as a whole is concentrated at definite points. The reactions produced in a complex structure by direct transfer of energy may be more selective than those brought about by the indirect action of highly reactive free radicals, and this may explain the much higher efficiency of direct action for the inactivation of viruses¹¹.

This communication is published by permission of the Director of the Atomic Energy Research Establishment. The investigation has been supported by a special grant from the Anna Fuller Fund and by grants to the Royal Cancer Hospital and Chester Beatty Research Institute from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service. AFTER-EFFECTS OF X-IRRADIATION OF DEOXY-RIBONUCLEIC ACID

By DR. B. E. CONWAY

Chester Beatty Research Institute, Royal Cancer Hospital, Fulham Road, London, S.W.3

THE change of viscosity of deoxyribonucleic acid (DNA) brought about by X-irradiation was shown by Taylor, Greenstein and Hollaender¹ to continue long after the termination of the irradiation. Butler and Conway² found that after irradiation of deoxygenated solutions of DNA the viscosity remained nearly constant after a small initial fall during the first hour or two. They therefore concluded that the 'slow' after-effect, following irradiation in oxygen, was due to a product of the primary radicals with molecular oxygen. Possible products are HO_2 radicals and molecular H_2O_2 , and it was shown that hydrogen peroxide, although present and responsible for some of the after-effect, was not capable of accounting for the whole of it. It was suggested that the remainder of the effect might be due to the slow decomposition of peroxidic derivatives of the nucleic acid.

Recently, Daniels, Scholes and Weiss³, using slightly different experimental conditions, observed an after-effect in deoxyribonucleic acid solutions irradiated *in vacuo*, which was about one-third of

that found with oxygenated solutions. They therefore suggested that the effect of oxygen was merely an enhancement of an effect which already occurred in its absence, namely, the slow hydrolysis of deoxy-pentose-phosphate internucleotide links made labile by oxidation by the radicals at the C_4' position on the pentose^{4,5}. The enhancement of this effect by oxygen they supposed to be due to elimination of back reactions, thus leading to an increased oxidation yield.

I have made experiments to ascertain the cause of this discrepancy between the results of Daniels, Scholes and Weiss⁴ and those of Conway and Butler^{5,6}.

Solutions of a highly polymerized specimen of DNA (0.1 per cent) were prepared *in vacuo* in an all-glass apparatus, in which water was distilled *in vacuo* into ampoules containing the DNA, from a vessel in which it had been previously deoxygenated by refluxing at atmospheric pressure in argon, made oxygen-free by passage through alkaline pyrogallol, and then over copper gauze heated to about 450° C. and finally through a trap in a solid carbon dioxide-ethanol mixture. The ampoules were detached and the deoxyribonucleic acid allowed to dissolve for about 36 hr.: the solutions were then irradiated with 140-kV. X-rays (half-value layer thickness 0.04 mm. copper) to give a dose of 10,000 r. at 166 r./min. Oxygenated solutions were prepared by bubbling oxygen through the solution for 15 min. immediately prior to the irradiation. The viscosity of the solutions was measured as soon as possible after the termination of the radiation in Frampton type viscometers at shear-rates between 50 and 250 sec.⁻¹. When the experiments were carried out under these conditions, I was able to reproduce the observations of Daniels *et al.*⁴; I examined a number of factors such as shaking the solutions for 12 hr. before radiation) introducing various types of grease, keeping the solutions in argon or nitrogen instead of *in vacuo* during the irradiations, but so long as the viscosity was measured directly (see below) on the irradiated solutions an after-effect of about one-third of that found in oxygen was usually observed (Fig. 1). However, when the experiment was carried out under the conditions which we used in our earlier work^{3,4}, namely, irradiation of solutions at 0.2 per cent concentration, followed by dilution to 0.1 per cent with twice-distilled water immediately after the irradiation and before the viscosity measurements were commenced, the after-effect *in vacuo* was largely sup-

pressed and was no greater than the slow change of viscosity which occurred after diluting a 0.2 per cent solution to 0.1 per cent. When the 0.2 per cent irradiated solutions were diluted, 1:1, with 0.1 N sodium chloride the viscosity was quite constant for 48 hr. (Fig. 2). Dilution, either with water or 0.1 N sodium chloride, of the 0.2 per cent solutions irradiated in oxygen did not eliminate the after-effect. The discrepancy in the results thus appears to be due to the fact that Daniels *et al.*⁴ measured viscosities of the solutions as irradiated, whereas Conway and Butler, for reasons of experimental convenience, diluted their solutions $\times 2$, after irradiation before the viscosity measurements were commenced.

The fact that the *in vacuo* after-effect can be largely eliminated by dilution raises the question whether the slow changes observed in this case in non-diluted solutions can be attributed to a chemical process at all, for example, to the slow hydrolysis of labile internucleotide linkages (see above) as suggested by Scholes and Weiss^{4,5}.

The viscosity of solutions of deoxyribonucleic acid at moderate concentrations is largely due to the interactions between the particles^{7,8} and is not related in a simple way to the length of the polynucleotide chain. It is possible to destroy the abnormal high viscosity without any appreciable change of molecular weight⁹. Viscosity changes cannot, therefore, be taken as solely due to breakages of the nucleotide chain resulting from the oxidation of the sugar; various lines of experimental evidence show that viscosity changes can occur by changes in the intramolecular hydrogen-bonding and in intermolecular interactions.

The elimination of the after-effect by dilution suggests that in the experiments without dilution the after-effect is largely the result of a slow readjustment or equilibration of the interactions between the particles due to their modification in shape, size and charge by the chemical processes occurring during the irradiation. Dilution with water or salt solution presumably immediately introduces much larger changes of interaction between the particles, so that the slow effects which would otherwise be apparent are no longer significant.

With regard to the large after-effect produced by irradiation of oxygenated solutions, the mechanism is complex; it is an undoubted fact that: (1) hydrogen peroxide is formed; (2) hydrogen peroxide is

capable of degrading irradiated deoxyribonucleic acid^{4,10}. In the mechanism of the after-effects discussed by Daniels *et al.*⁹, this effect of hydrogen peroxide in the oxygenated solution has not been considered. It is quite possible that some part of the after-effect observed in oxygen is due to slow hydrolysis of sugar phosphate groupings labilized by oxidation at the C_{4'} position as Scholes and Weiss suggest.

However, the suggestion by these authors, that in oxygen the formation of unstable peroxidic intermediates of the deoxypentoses in nucleic acid may be more important than direct oxidation by OH radicals, is not unlike our own^{4,10}.

It seems likely that all three processes, namely, the formation of labile phosphate esters, the slow decomposition of peroxide intermediates and the interaction of hydrogen peroxide, formed during the irradiation in oxygen, with the deoxyribonucleic acid damaged by radiation¹⁰, may be involved simultaneously in the after-effect observed in oxygenated solutions. The recent proposal by Watson and Crick¹¹ of a double-chain helical structure for deoxyribonucleic acid, in which the chains are held together by hydrogen bonds between the heterocyclic bases, makes possible the consideration of another type of process which might occur slowly after initial damage to the chains by certain radicals. If the chains of a linked pair are broken at some points not immediately opposite one another, and some damage, for example, a deamination, ring fission, etc.^{4,12}, is caused to the bases, a slow rearrangement such as untwining or collapse of the helical rod-like structure might occur during a period of time after the initial damage.

It might have been expected, on the theory advanced by Daniels, Scholes and Weiss, that if the greater after-effect in oxygen is due to an enhanced oxidation, the primary effect of irradiation would also be greater in this case. Daniels *et al.* state, however, that the primary effect of irradiation in oxygen is less (about 50 per cent) than that *in vacuo*. It is not easy to see how they reconcile this observation with their theory; their results could only be explained if it is supposed that hydrogen atoms are much more effective in immediate depolymerization of deoxyribonucleic acid than the HO₂ radicals formed from them in oxygenated solutions. In our own experiments, on the other hand, it has consistently been found that viscosities measured very soon after irradiation *in vacuo*, nitrogen or oxygen are closely similar, in agreement with the observations of Smith and G. O. Butler¹³, and Limperos and Mosher¹⁴.

A further experiment has been designed especially to test this point again. 0.1 and 0.2 per cent solutions of deoxyribonucleic acid were made up *in vacuo* in one limb of double ampoules in the form of an inverted U. When the nucleic acid was dissolved completely, the solution was divided equally between the two ampoules by tipping the U-tube. This procedure was used in order to make the comparison on identical solutions, since some variations occur in the viscosity of solutions of deoxyribonucleic acid of the same concentration made up separately at different times. The solution in one side of the double ampoule was then irradiated, still *in vacuo*, with 10,000 r., while the other limb was shielded in a thick lead pipe. After the radiation, the viscosity of the solution was measured between 50 and 250 sec.⁻¹ in the Frampton viscometer. Oxygen was then passed into the second half of the solution contained in the other ampoule, and this was then

Fig. 3. Primary effect of X-irradiation (10,000 r.) *in vacuo* and oxygen
 x, control; ●, 0.1 per cent *in vacuo*; ○, 0.1 per cent in oxygen;
 □, 0.1 per cent after dilution from 0.2 per cent, *in vacuo*;
 Δ, 0.1 per cent after dilution from 0.2 per cent, in oxygen

irradiated similarly and its viscosity determined. After the irradiation, the viscosity of the solution irradiated *in vacuo* was only 4 per cent less than that of the solution irradiated in oxygen (Fig. 3). We cannot, therefore, agree that the primary effect in oxygen is greatly different from that *in vacuo*, as maintained by Daniels, Scholes and Weiss. These results suggest, then, that the after-effect in oxygen is due mainly to distinct processes not involved to any great extent in the primary effect in either oxygen or *in vacuo*.

Acknowledgments. I wish to thank Prof. J. A. V. Butler for his interest in the work and for many helpful discussions and suggestions, and Dr. L. F. Lamerton for providing facilities for carrying out the X-irradiations. Temperature Acclimatization in Insects

Among the voluminous literature on temperature and poikilothermal activity, an occasional paper is found dealing with temperature acclimatization. The majority of work has been carried out with fish.

With respect to insects, Mellanby^{1,2} showed for a number of species that their activity at low temperatures was modified by their previous thermal history, thus indicating that insects became acclimatized to temperature. Thermal acclimatization experiments have been carried out with the German cockroach, *Blattella germanica* L. and some of the experimental evidence is presented below.

The relation between acclimatization temperatures and activity at low temperatures above freezing is shown in Fig. 1. It is evident that insects kept at 15° C. are able to remain active at temperatures at which others from 25° C. and 35° C. are immobilized by cold. Acclimatization to cold is not an unlimited process, which is illustrated in Fig. 2, where cold immobilization or 'chill-coma' temperatures are plotted against their corresponding acclimatization temperatures. The 'chill-coma' temperature of *B. germanica* acclimatized at 10° C. is the same as for those acclimatized at 15° C. This suggests that acclimatization is only possible within a certain temperature-range.

Fig. 1 Relation between acclimatization temperatures and activity at low temperatures for males of *B. germanica*

Fig. 2 Relation between 'chill-coma' temperatures and acclimatization temperatures for males of *B. germanica*

Experiments have also been carried out on survival at 7° C. of *B. germanica* acclimatized at 35° C., 25° C. and 15° C. Insects from 15° C. lived longer than those from either 25° C. or 35° C.; the 35° C. group died most quickly. This implies that much of the previous work on cold-death points at temperatures above freezing is invalidated. The cause of death at low temperatures is unknown, but insects immobilized by cold for a given period showed signs of a nervous disturbance which was not reversible.

This and other phases of the work will be published more fully elsewhere.

Acclimatization and the Thermal Death Point in Insects

Insects, like other cold-blooded animals, are active over a range of temperature, limited below by the chill coma point, and above by the heat coma point (closely related to the thermal death point, that is, the upper lethal temperature, for they cannot recover from long periods of heat coma). On the whole, the heat coma point is higher for insects from warm regions, and the chill coma point is lower in those from cool regions.

The chill coma temperature can be readily altered. I showed some years ago that in a number of species exposure for as short a period as 24 hr. to warmer or cooler conditions within the normal range will modify the chill coma point substantially, in some species by as much as 7.5° C.^{1,2}

I now find that the heat coma point and the thermal death point can similarly be rapidly changed by keeping insects at different temperatures for periods of only 20 hr.; longer exposure gives no further adaptation. Thus, in the mealworm, *Tenebrio molitor*, larvae from cultures kept at 37° C. for 24 hr. have a thermal death point, for a one-hour exposure, of 44° C.; those kept at 30° C. or below have a thermal death point of 42° C. The results for larvae of the mosquito *Aedes aegypti* are very similar. Two facts are apparent when these results are compared with the low-temperature experiments: (a) the range over which the thermal death point can move is much smaller than that over which the chill coma temperature can be changed; (b) substantial changes in the thermal death point are caused only by previous exposures to temperatures towards the top of the range over which the insects can survive, whereas low-temperature adaptation occurs over the whole range.

Insects acclimatized to high temperatures thus survived exposures which killed unacclimatized insects. It was noticed, however, that they did not continue their development and moult or pupate at the same time as unheated controls. It seems that sublethal exposures to heat may destroy the internal secretions which control these processes. I showed³ that if the blow-fly larva *Lucilia sericata* is kept at a high temperature for several days it goes into diapause, while controls pupate. Wigglesworth⁴ has similarly shown that at temperatures above the optimum the bug *Rhodnius prolixus* does not moult.

The experiments described here show that much briefer exposures to high temperatures interrupt development, but that after a delay (of perhaps a month in *Aedes*) normal pupation occurs and adults are then produced after the usual interval.

This extended life-history in insects may be of practical importance. In Nature, insects may often be exposed to temperatures similar to those used in these experiments, and if this causes a substantial prolongation of the life-history, it may give rise to unexpected emergences of insects which are important vectors of disease or pests of stored products.

An Acidogenic Carotenoid in a Bathypelagic Nemertean Worm

CERTAIN brightly coloured littoral nemerteans contain carotenoids, and it is likely that most deep-sea species of similar coloration likewise store this class of biochrome¹.

Recently, there arose a rare opportunity to examine briefly the red-orange pigment from three freshly collected specimens of *Nectonemertes mirabilis* Verrill (one immature male and two females, 30–34 mm. long and 5 mm. wide). These were taken in a depth haul from 1,200 m. to the surface in the Santa Barbara Passage off the coast of Southern California by Dr. N. T. Mattox at the Allen Hancock Foundation, and were presented to Prof. W. R. Coe of the Scripps Institution, who identified them as members of this widely distributed species, usually encountered at depths from 500 m. down, in the North and the South Pacific Ocean.

The specimens, fixed in dilute formalin, then preserved in 70 per cent ethanol, were examined within a week after capture. The deep red-orange pigment was concentrated in oil droplets in the digestive diverticula. In view of the unlighted habitat and the microcrustacean diet of this worm, it was of special interest to learn whether, as in numerous other marine carnivores, its richly stored pigment might belong to the oxygenated carotenoids¹.

The preserved worms had lost none of their bright colour, but substitution of absolute ethanol readily leached the pigment out, imparting a red-orange colour to the solvent and leaving the animals quite pale. The pigment was completely epiphasic, migrating quantitatively from the alcohol into light petroleum to give a yellow solution. However, after an hour's exposure to warm ethanolic potassium hydroxide, the pigment showed quantitative hypophasic behaviour, thus reflecting the absence of carotenes and the original presence of esterified xanthophylls. Dilution effected the migration of a trace of yellow pigment into the petroleum, while the more copious red component now separated as a potassium salt at the liquid interface. In its preferential solubility in alcohol, and in its reversible transference from alkaline or neutral alcohol to petroleum,

Absorption curve of acidogenic carotenoid derived from an ester occurring in *Nectonemertes mirabilis* Verrill

the yellow component behaved like a neutral xanthophyll. Its quantity was insufficient for further study.

The red interfacial salt was washed with additional petroleum and was then readily dissolved in this solvent containing a little acetic acid. The yellow petroleum solution displayed, on shaking with water, the transient pinkish emulsion which characterizes other acidogenic carotenoids, such as astaxanthin and metridioxanthin². The acid-free petroleum solution was evaporated in an inert atmosphere and the deep orange residue was dissolved in redistilled pyridine (b.p. 114–116° C.). This red-orange solution exhibited a single, discrete absorption peak whose steep, symmetrical shape and maximum at 490 mμ differentiated it from astaxanthin or its artefact, astaxene, which show a less sharp maximum at 500 mμ in the same solvent (Beckman photoelectric spectrophotometer; see accompanying figure). In its spectrum the nemertean pigment recalls a similar acidogenic carotenoid from the marine shrimp *Hippolyte*³ and another from the anemone *Metridium*⁴.

Evidently this deep-sea pelagic ribbon-worm owes its bright red-orange colour to the presence of an acidogenic carotenoid ester, related to but not identical with astaxanthin. The principal carotenoid and the accompanying traces of esterified neutral xanthophyll doubtless originate from the animal's consumption of planktonic crustaceans and other pelagic fauna. The finding of rich stores of oxygenated carotenoids, unaccompanied by any carotene hydrocarbons, adds to the growing list of xanthophyll-selecting marine carnivores¹, a widely occurring species the habitat of which is limited to great oceanic depths.

I acknowledge the generosity and help of Prof. Wesley R. Coe, and the welcome co-operation of Dr. Norman Millott in conducting the spectroscopic examination.

In Vitro Cultivation of Mouse Ascites Tumour Cells for Virus-Host Cell Studies

KLEIN^{1,2} has found that the so-called Ehrlich ascites tumours of mice offer several advantages over solid tumours for studying the effect of a substance on the growth-rate, on nucleic acid content and on the cytomorphology of neoplastic cells. These advantages have been applied lately by a number of investigators^{3,4} to studies dealing with the effect of viral infection upon the neoplastic process and with the adaptation of virus to the ascitic cells⁵. These investigations have all been carried out in the peritoneal cavity of the mouse. An *in vitro* technique which may prove feasible for similar studies, particularly host-cell virus studies in neoplastic cells cultivated apart from the animal, was recently developed in our laboratory.

Ascites cell suspensions were freshly removed from tumorous Webster-strain white mice, centrifuged at 2,000 r.p.m. for 15 min. and the supernatant decanted. The cells were then resuspended in a nutrient medium composed of 50 per cent ox serum ultrafiltrate, 10 per cent chick-embryo extract and 40 per cent Hanks's balanced salt solution with 0.002 per cent phenol red indicator. Two hundred units of penicillin and 100 µgm. of streptomycin were added at first to preclude contamination. 1-c.c. aliquots were dispensed into Porter flasks in which were incorporated glass coverslips (11 mm. x 22 mm.) and the flasks incubated at 36° C. The medium was renewed daily for the first four or five days, the pH during this period showing diminutions from the 7.5 of the fresh medium to 6.6-6.8 within twenty-four hours. The fluid phase in the first twenty-four hours turned a chocolate-brown, due most likely to denaturation of haemoglobin from red blood cells carried over with the ascitic fluid. Thereafter, the medium was renewed at weekly intervals for six weeks. Coverslips were withdrawn from random Porter flasks at the time of fluid renewal and stained by the May-Grünwald and Giemsa method⁶.

Microscopic examination of the stained coverslips indicated that the ascites tumour cells maintained their usual appearance for at least the first week of culture. In the following weeks increasing numbers of cells showed progressive degeneration as manifested by increasing cytoplasmic vacuolation and karyoplasmic fragmentation. However, by the end of the sixth week there were still a considerable number of cells presenting a normal appearance. In this connexion, it should be mentioned that Hull⁷, employing a subculture technique, has succeeded in serially culturing a line of ascites tumour cells for more than eight months. The frequency of blood cells and wandering cells was of the order of only a few per cent and these were readily distinguishable.

The utilization of cells morphologically, functionally, and potentially alike would permit a far more exact evaluation of host-cell reactions with, and responses to, specific viruses under conditions of culture. The Ehrlich ascites tumour cells being maximally dedifferentiated⁸ do not manifest the protean ensemble of morphological forms so frequently observed with cells in culture, a phenomenon ascribed by Weiss⁹ to 'modulations'. In addition to the advantage of uniform cells, which is ordinarily provided only by continuous cultures maintained over long periods of time, the absence of a fibrin clot affords the cells a maximum exposure to the viral particles in the fluid phase. Also, the ready manipula-

tion and staining of the coverslips upon which the cultures grow permit a sequential study of cytomorphological development and change.

This investigation was aided by a fellowship from the National Foundation for Infantile Paralysis.

Vaccination against Haemorrhagic Septicaemia of Bovines

HAEMORRHAGIC septicaemia kills many thousands of cattle and buffaloes in Asia each year. Vaccination with conventional products such as formalin-killed cultures of *Pasteurella multocida* have not been considered an effective form of prophylaxis although practised for the past thirty years or so. The serological typing of strains of the causative organism and studies on its antigenic structure have not been pursued extensively in Asiatic countries in the past. In recent studies sponsored by the Food and Agriculture Organization of the United Nations, strains of *P. multocida* recovered from field cases of the disease in south-east Asia were typed by the mouse protection method of Roberts¹; 14 Burmese, 3 Indian, 2 Pakistanian, 2 Malayan, 2 Siamese and one Indonesian strains were found to be type I. Only one other serotype was recovered from bovines—a single strain of type IV from Burma.

P. multocida type I is a small-capsule variety of *Pasteurella* which, unlike the large-capsule varieties, is not decapsulated by bull testis hyaluronidase. During the first and second subcultivations after primary isolation, type I strains are agglutinable only by low dilutions of homologous antisera, but in subsequent subcultivations agglutinability is increased by up to a hundredfold without any obvious change in morphology. At the same time, agglutinability of cells in cetyl trimethyl ammonium bromide declines. These facts suggest that type I strains may have an antigen analogous to the 'Vi' of *Salmonella typhosa*. Cultures relatively inagglutinable in homologous antisera have been provisionally called 'phase I' cultures and are used for vaccine production. Simple formalin-killed bacterins made from 'phase I' cultures have not been highly successful as prophylactic agents, only 1 of 11 and 11 of 16 bovines having been protected against a 25,000 lethal dose challenge four weeks after inoculation. However, when an equivalent dose of 'phase I' cells, formalin-killed, was incorporated in a mineral oil-lanolin emulsion and injected intramuscularly in a dose of 2 ml. the results were greatly improved. In a series of small experiments in Burma and Siam a total of 36 of 39 cattle and buffaloes were protected against 25,000-200,000 lethal doses injected subcutaneously four to five weeks after inoculation with adjuvant 'phase I'

vaccine. One out of five cattle inoculated with adjuvant 'non-phase I' vaccine survived comparable challenge. Animals with naturally acquired immunity were detected and eliminated from the experiments by a serum agglutination test using 'phase I' cells as the agglutinating suspension. Every one of twenty control unvaccinated cattle and buffaloes used in these experiments succumbed to the challenge dose of live culture. Experiments are continuing on a larger scale to test the duration of immunity and its effectiveness under field conditions. Details of the experiments mentioned above are being reported in full elsewhere.

Sodium : Potassium Ratio in the Hypophysis

It was observed in 1947¹ that the thyroid gland of the mouse specifically accumulates intravenously injected uranin (sodium-fluoresceinate); large concentrations of sodium are known to be present in the thyroid colloid. Similarly, we observed the appearance of uranin upon intravenous injection of its 5 per cent solution in high amounts in the hypophysis of mice, particularly in the posterior lobe of this gland².

The affinity of elements of the 'extracellular' group in general for the pituitary is suggested by the specific accumulation of radioactive iodine in its posterior lobe^{3,4}. It parallels the high molecular concentration of calcium and aluminium in the thyroid gland⁵ and of electropositive organic bromine compounds in the pituitary⁶.

Assuming a parallelism between the high sodium-levels and uranin accumulation, we determined by flame photometry the sodium and potassium content of the posterior and anterior lobes of the pituitary in large animals.

The organs were obtained at the slaughter house and placed in a deep-freeze box within 50-60 min. after death. We analysed glands from calf, cow, ox and steer; in the case of lambs' glands, the size of the glands available did not permit us to analyse the lobes separately. Weighed amounts of 0.8-1.5 gm. were heated to ash in a platinum crucible. The ash was taken up in a few drops of concentrated hydrochloric acid and again reduced to ash at red heat. The residue was then made up to 10 ml. with water and the appropriate dilutions were analysed in the flame photometer (apparatus of Process and Instrument Co., Brooklyn).

The moisture content, determined by drying at 105°, of the posterior lobe was, with a single exception, within the range of 71.5-75 per cent, the ash content 1.12-1.48 per cent. The corresponding figures for the anterior lobe were: moisture 76-81 per cent, ash 0.68-1.05 per cent.

The accompanying table summarizes the results, giving the concentration of the elements in milliequivalent values/100 gm. of tissue and also the molar quotients K/Na. Except for the posterior lobes in Nos. 1 and 3, the anterior lobe in No. 5 and the whole gland in No. 9, there is a consistent prevalence of sodium over potassium.

The predominance of sodium, and possibly of the entire 'extracellular' group of elements, seems to be

SODIUM AND POTASSIUM CONCENTRATIONS IN THE HYPOPHYSIS

No.	Animal	Posterior lobe		K/Na	Anterior lobe		K/Na
		Milli-equivalents per 100 gm. K	Na		Milli-equivalents per 100 gm. K	Na	
1	Calf	5.84	3.40	1.53	1.18	1.23	0.96
2	"	4.45	5.74	0.78	1.24	4.04	0.33
3	Cow	5.16	5.04	1.02	2.27	3.25	0.70
4	"	5.10	5.70	0.89	3.87	4.18	0.93
5	Ox	4.55	5.05	0.90	6.80	5.10	1.36
6	Steer	5.06	7.55	0.75	4.44	5.12	0.87
7	"	5.10	7.83	0.65	3.31	5.25	0.63
8	"	4.04	6.07	0.61	2.78	4.52	0.53
9	Lamb (whole organ)	7.65	4.54	1.68			
10	"	4.06	6.80	0.60			

particularly pronounced in the steer. The lowest potassium values were shown in the anterior lobe of the calf. We believe that the prevalence of sodium is a characteristic feature of the hypophysis throughout the mammals.

Comparisons of potassium and sodium content of animal organs⁷ show predominance of potassium in most of the internal organs and the highest values in the musculature and the erythrocytes. The lowest K/Na quotients, on the other hand, are shown by blood plasma, bone and skin. Like the thyroid, the pituitary gland belongs, according to our determinations, to this latter group of organs. The prevalence of sodium over potassium is shared in most cases by the posterior and anterior lobes.

Diabetogenic Action of Pancreatic Glucagon

In previous experiments it has been shown that pancreatic glucagon, produced in the A cells of the pancreatic islets¹, significantly increases the blood-sugar-level and the urine glucose of intact rats, forcibly fed on a high carbohydrate diet; in these conditions glucagon also augmented the diabetogenic effect of pituitary somatotrophic and corticotrophic hormones as well as of cortisone. Combined treatment with glucagon and cortisone was the most effective in provoking a temporary diabetic condition².

We have now carried out experiments on intact, normally fed rats with either cortisone or glucagon alone and with combined treatment, in order to investigate further the possible role of glucagon in the disturbances of the carbohydrate metabolism.

Fifty-four male adult rats, weighing 118 ± 2.3 gm. at the start of the experiment, were fed on a synthetic diet containing 25 per cent proteins, 63 per cent

carbohydrates, 10 per cent lipins, 2 per cent McCollum salt mixture and supplements of vitamins and lipotropic factors; water was allowed *ad libitum*. The intake of food was kept constant, 15 gm. per 100 gm. of body-weight being allowed daily and regularly consumed. The animals were kept in metabolism cages and the urine collected daily.

The animals were divided into three groups: 14 rats were treated with cortisone acetate ('Cortone' Merck), 5 mgm. daily subcutaneously; 16 with glucagon 1 mgm. of protein daily intraperitoneally in two divided doses; and 24 with cortisone plus glucagon, respectively 5 and 1 mgm. daily. Impure glucagon was prepared from alkali-inactivated insulin, according to the method of Sutherland and co-workers³; an amorphous insulin, rich in this factor and kindly supplied by Dr. W. R. Kirtley, Eli Lilly and Co. (lot ML 509948), was used for its preparation. Our preparation, tested intravenously in rabbits and on liver slices *in vitro*, showed a high hyperglycaemic and glycogenolytic activity. The treatment lasted twenty days. Fifteen days after the beginning of treatment glucose and insulin tolerance tests were carried out on ten animals per group; in the morning 0.5 gm. of glucose per 100 gm. of body-weight was administered by stomach tube, and blood samples taken from the tail 0, 1, 2 and 3 hours after the tube feeding; in the afternoon 0.1 I.U. of insulin per 100 gm. of body-weight was injected subcutaneously and blood samples taken in the same way. At the end of the experiment the animals were weighed and killed by sudden decapitation; the pancreas was fixed in Susa fluid and studied morphologically in sections stained with the Gomori chrome-haematoxylin and phloxyn method⁴.

During the experimental period the body-weight decreased 0.5 ± 0.1 gm. daily in cortisone group and 0.9 ± 0.2 gm. daily in cortisone plus glucagon group, whereas it increased 2.3 ± 0.2 daily in glucagon group. The occurrence of spontaneous infections in respiratory and digestive tracts was high in cortisone group (36 per cent) and was not evidently reduced by the simultaneous administration of glucagon (30 per cent); no infections were observed in glucagon group.

A dosable glycosuria was never observed in cortisone and glucagon groups, while the animals having combined treatment displayed constantly an appreciable glycosuria, beginning at the 7-9th day of treatment and gradually increasing in the following days up to 50 per cent. After stopping the treatment glycosuria promptly disappeared. The fasting blood sugar was 164 ± 18 mgm. per cent in the animals having combined treatment, while in cortisone and glucagon groups it was respectively 84 ± 8 and 105 ± 7 mgm. per cent.

The hourly changes of the blood sugar in the glucose tolerance tests are recorded graphically in the accompanying figure. From this it appears that the tolerance was practically normal in cortisone and glucagon groups, while in animals having combined treatment it was evidently lowered. As regards the insulin test, the combined treatment only resulted in some resistance to the insulin.

At the histological examination of the pancreatic islets, no striking regressive changes were demonstrable; a mild degree of hydropic degeneration was sometimes detectable in B cells of the animals having combined treatment. In all groups the B cells were hypertrophied and showed poorly granulated cytoplasm; mitotic figures were exceptionally seen. The A/B cells ratio was unchanged in cortisone group,

while in the two other groups the A cells were decreased in number, especially in the smaller islets, and showed hypotrophic changes.

From the foregoing results it appears that impure glucagon in itself cannot be considered as a diabetogenic factor in the intact rat; however, it can potentiate the diabetogenic effect of other hormones, such as cortisone, thus determining a temporary diabetic condition.

It seems that in normal rats the hyperglycaemic effect of glucagon is easily controlled through an extra-secretion of insulin; on the contrary, in cortisone-treated animals, where a high storage of liver glycogen occurs, glucagon can release higher amounts of glucose in the blood stream, thus inducing a relative insulin deficiency. Nevertheless, there are other possibilities for explaining our results: for example, an inhibitory effect either of glucagon or of cortisone on the peripheral utilization of glucose or a direct inhibitory effect on the insulin secretion might be the mechanisms here involved. At present, our knowledge of the physiological activities of glucagon is too slight for giving a complete explanation of the observations.

Abnormal Accumulation of 3-Hydroxykynurenine in the Mutant 'Aka-Aka' of Silkworm

RECENTLY, Inagami¹ obtained (isolated) a mutant of *Bombyx mori*, proved that it is based upon a single recessive gene and called it 'Aka-Aka' (*rb*), which means red colour in Japanese, for the skin of the mature larva is red and its body fluid turns fairly red when exposed to air in contrast with the blackening of the normal type.

In order to investigate the mechanism of this red colouring we dialysed the body fluid gathered from several larvae of this mutant against diluted acetic acid, and the external dialysate, which showed a strong ultra-violet absorption band and an intensive diazo reaction (red), was concentrated under reduced pressure in an atmosphere of hydrogen. The resultant syrup was chromatographed on No. 50 Töyō filter paper (40 cm. $\times$ 40 cm.) using water-acetic acid-butanol (ascending method), and the chromatogram was observed under ultra-violet light; only one main fluorescent band was detected between R_F values of 0.30 and 0.38. This band was cut out and, after elution with water, we carried out paper-chromatography, colour tests and ultra-violet absorption spectrography with the elute. As indicated below, the substance concerned was shown to be 3-hydroxykynurenine. It gave a green fluorescence, the ninhydrin reaction, a strong diazo reaction (brownish-red, turning slowly to brown), Ehrlich's reaction with aldehyde (pink) and a ferric chloride colour test (brown); R_F in butanol-acetic acid, 0.39; R_F in 70 per cent propanol, 0.31; R_F in benzene-butanol-methanol-water (1:1:2:1), 0.38; absorption maxima (pH 3.0) 270 and 370 μ . The same values as above were obtained with an authentic sample of 3-hydroxykynurenine.

In accordance with the strong diazo reaction of the external dialysate (see above), the estimated value for 3-hydroxykynurenine in the body fluid, which was determined by another method¹, was strikingly high, amounting to 15~20 times as much as that in the White-2 mutant or the normal type.

The abnormal colouring of the 'Aka-Aka' mutant is presumably due to extraordinary accumulation of 3-hydroxykynurenine, for Inagami² could induce the red-colouring by addition of this substance to the dopa-tyrosinase system, differing from the case without addition of 3-hydroxykynurenine (in this case, as is commonly known, the reaction mixture turns black).

We thank Prof. T. Sakan for a gift of 3-hydroxykynurenine.

Detection of Adenine Carbon-14 in Deoxyribonucleic Acid by Autoradiography

THE standard procedure for detecting phosphorus-32 in deoxyribonucleic acid by autoradiography is to hydrolyse the smears or sections in N HCl at 60° C. for 6-10 minutes. The acid hydrolysis removes RNA and most of the non-DNA phosphates.

Adenine carbon-14 administered *in vivo* or *in vitro* will be taken up by both nucleic acids. Since, however, the usual biochemical procedure to isolate the purine bases from the nucleic acid solutions is

Adenine carbon-14 in deoxyribonucleic acid. Human bone-marrow cells cultured *in vitro* for 24 hr. in 0.5 μ Ci/ml. adenine-8-¹⁴C. Smears fixed in alcohol and hydrolysed in N hydrochloric acid, 60° C., 6 min. Stained autoradiographs. ($\times$ 1,400)

acid hydrolysis, the histochemical separation of RNA from DNA is usually performed by ribonuclease.

Current work on the nucleic acid metabolism of human bone marrow cells *in vitro* necessitated the use of adenine-8-carbon-14. Since the RNA turnover was found to be higher in the nucleus than in the cytoplasm, the autoradiograph above the nucleus cannot give even approximate information on the rate of DNA synthesis unless RNA is removed from the cells.

The preparation of ribonuclease is somewhat cumbersome and batches may vary in activity, mainly due to the amount of impurity present in the preparation. The enzyme is sensitive to pH, which also has to be controlled, during incubation of the enzyme, with smears or sections.

In order to find a simple and easily standardized procedure it was decided to investigate the action of acid hydrolysis on DNA adenine in smears. Although the literature described the isolation of purine bases from nucleic acid solutions by acid hydrolysis, no experimental evidence was found that the same effect will occur in alcohol-fixed smears on brief hydrolysis.

Human bone marrow cells were cultured *in vitro* in 0.5 μ Ci/ml. adenine-8-carbon-14 for 12-24 hours. The smears were fixed in 95 per cent alcohol and one batch was treated with ribonuclease (2 mgm./ml. for 2 hr. at 37° C.), the other with N HCl at 60° C. for 6-10 min. The slides were coated, using stripping film, and stained autoradiographs were made, as described elsewhere¹. It was found that in the smears six minutes hydrolysis gives identical pictures to those of the ribonuclease. The grain counting over the nuclei of the acid-hydrolysed or ribonuclease-treated cells indicates an uptake of the order of $10-15 \times 10^4$ carbon-14 atoms in twenty-four hours. Since the total number of DNA adenine + guanine molecules per nucleus is of the order of 0.85×10^{10} this implies a very high degree of labelling of the DNA. More than seven minutes hydrolysis tends to decrease the strength of the autoradiographs; presumably some purine bases are removed from the DNA by prolonged hydrolysis. The application of deoxyribonuclease prior to acid hydrolysis renders the smears completely free from carbon-14 activity.

The photomicrographs illustrate the pictures thus obtained with acid hydrolysis. It is a procedure easy to standardize and has been found a simple method for the autoradiographic determination of DNA adenine.

This work is part of an investigation carried out with a grant from the British Empire Cancer Campaign. Grateful acknowledgment is made to Dr. S. R. Palo, of the Radiopathological Research Unit

of the Medical Research Council, Hammersmith Hospital, for the samples of ribonuclease and deoxyribonuclease.

Presumed Antitubercular Activity of 4-Amino-6-Hydroxy-*iso*-Phthalic Acid

AMONG the numerous compounds obtained by modifying the chemical molecular structure of *para*-amino-salicylic acid, our attention has been directed to 4-amino-6-hydroxy-*iso*-phthalic acid¹, especially concerning the discordant opinions in respect of its antitubercular activity. In fact, while Bavin *et al.*² have found an activity corresponding to that of the *para*-amino-salicylic acid, according to Beyerman and Alberda³ the compound should be 2-5 times less active than *para*-amino-salicylic acid.

Investigators¹ have generally obtained this compound from *m*-aminophenol by means of a Kolbe reaction. In this reaction the principal product formed is *para*-amino-salicylic acid, while the 4-amino-6-hydroxy-*iso*-phthalic acid has to be isolated as a side-product.

Recently, Beyerman and Wieleaert⁴ have described a synthesis with 4,6-dinitro-*m*-xylene as starting material, and have found the same bacteriological activity as before.

We have synthesized this compound by another route with the view of examining these discrepancies.

For this purpose we nitrated the 1,2,4-xylidine with concentrated sulphuric acid and fuming nitric acid to 4-amino-6-nitro-*m*-xylene (m.p. 123°)⁵, then the NH₂-group was substituted by diazotiation by an OH-group which was transformed into the methyl-ether by suspending the solid sodium compound in xylene and by reacting with dimethylsulphate (yield 63 per cent). The two OH₂-groups were oxidized with KMnO₄ in a current of carbon dioxide (yield 50 per cent). By etherifying, Maltese⁶ has obtained a yield of 25 per cent only, and by oxidizing with KMnO₄ but without carbon dioxide he obtained a mixture of mono- and di-carbonic acids which was scarcely separable. The splitting of the etheral bond has been worked out with hydrogen bromide in acetic acid (glacial) (yield 63 per cent), m.p. 265° (crystallized from water). Calc. for C₉H₇NO₃: C, 42.30; H, 2.22. Found: C, 42.47; H, 2.14.

Successively, the nitro compound has been reduced to an amine with platinum oxide in alcohol; m.p. 212° (crystallized from diluted alcohol). Calc. for C₉H₉NO₃: C, 48.73; H, 3.58; N, 7.10. Found: C, 48.91; H, 3.22; N, 7.16.

For identification, we have transformed the compound into dimethyl 4,6-dimethoxy-*iso*-phthalic acid, as has already been done by Beyerman and Alberda³. This compound had a melting point of 147-148° C., in accordance with the literature⁶.

With the compound so prepared, inhibitory concentrations have been worked out in Youmans's medium with *M. tuberculosis*, strain H₃₇Rv, by inoculating 0.01 mgm. for 1 ml. of medium.

The results, read after fifteen days of incubation at 37°, have shown that for the *para*-amino-salicylic acid the minimal quantity to inhibit the growth is 0.1 mgm./100 ml., while for 4-amino-6-hydroxy-*iso*-phthalic acid it is 5 mgm./100 ml.

Therefore, the compound has been found to be much less active than described in the literature, and for this reason we suppose that other authors have worked with a product which was insufficiently pure and which contained other more active compounds.

Methyl Proline in Young Apple Fruits

It was recently suggested that a 'new' amino-acid isolated from the apple fruit was a methyl proline¹. This acid (called *D*₁ in the original communication) has now been compared with an authentic specimen of γ-methyl proline kindly supplied by Prof. F. C. Steward, of Cornell University. The positions occupied by these two acids on two-dimensional chromatograms (phenol ammonia-butanol-acetic acid-water) were found to be identical. Mr. J. K. Pollard in Prof. Steward's laboratory has also found the two compounds to superimpose on collidine-lutidine: phenol chromatograms. The two compounds (*D*₁ and γ-methyl proline) give identical colour reactions on paper chromatograms with ninhydrin (a yellow-orange colour) and with isatin (a pure blue colour developing at the same rate with both acids). Not more than ~17 mgm. of *D*₁ were obtained from 70 kgm. of young Worcester Pearmain apples, and elementary analysis on a sample containing traces of inorganic salt gave the following: C, 53.6 per cent; H, 8.17 per cent; N, 9.7 per cent. Assuming this indicates a C₉ compound with an empirical formula of C₉H₁₁O₃N, and correcting the analyses for ash gives: C, 55.8; H, 8.5; N, 10.1; methyl proline requires: C, 55.8; H, 8.5; N, 10.8 per cent.

It has already been shown that this acid is not the isomeric piperidine-2-carboxylic acid². In the Cornell laboratory, using washed and buffered papers, authentic γ-methyl proline was readily separable from pipecolic acid in butanol acetic chromatograms (γ-methyl proline, *R_F* = 0.259; pipecolic acid, *R_F* = 0.214). In the Ditton Laboratory, *D*₁ was not separable from pipecolic acid in butanol-acetic chromatograms. Therefore, this evidence alone is inconclusive. (It was unfortunately not possible to compare *D*₁ with the γ-methyl proline under the Cornell conditions.) The possibility is thus not ruled out that the material *D*₁ is any one of the possible methyl prolines. The constitution suggested by Grassman and von Arnim³ for the blue-coloured compound formed between proline and isatin does not help here since β- and γ-positions in the pyrrolidine rings are not involved.

Circumstances make it unlikely that further quantities of the acid will be obtained from the apple in this Laboratory in the near future; the object of this communication is to stimulate the search for methyl proline in other plant material.

A Histochemical Property of the Argentaffin (Kulschitsky) Cells

BAKER¹ introduced in 1946 a carefully standardized technique, developed from the Smith-Dietrich test, for the detection of lipines. In a later communication² he claimed that this modification (the acid-haematein test), controlled by his pyridine-extraction test, allows histochemical recognition of phospholipines. This was confirmed by Cain³ while working in Baker's laboratory.

Casselman⁴ applied this technique to certain synthetic enantiomeric α -phosphatidic acids, α -phospholipines, and related compounds, and to highly purified, natural lipine fractions, as well as to an additional 123 other substances: only phospholipines and certain phosphatidic acids gave positive results. His findings, while confirming Baker's claim, also suggested that "the entire phospholipine molecule may not be essential because some phosphatidic acids also give true positive reactions" (that is, positive in the acid-haematein test and negative in the pyridine-extraction test).

In his earlier communication, Baker observed that the Paneth cell granules in mouse intestine gave a positive though "rather weak" reaction which was negative in pyridine-extracted tissue.

In the intestine of two species (man and guinea pig) I have found that the argentaffin cells give a positive reaction with the acid-haematein test and a negative one in the pyridine-extraction test. As is well known, these cells in man are packed with infra-nuclear granules, which reduce solutions of ammoniacal silver nitrate with resulting deposition of silver on them⁵. The accompanying illustration shows such cells in a human appendix stained by Baker's acid-haematein method. (They are unstained in the pyridine-extraction test.)

This test has also been applied to human post-mortem material fixed 1½ hr. after death, with equally successful results. The argentaffin cells in guinea pig intestine likewise give clear-cut positive results.

Sections of gelatin-embedded, formalin-fixed tissue from a surgically removed argentaffin (carcinoid) tumour of the ileum in an elderly male were immersed in cold 5 per cent potassium dichromate-1 per cent calcium chloride solution for eighteen hours, followed by further treatment with this mixture at 60° C. for twenty-five hours, and then treated as directed in Baker's test. Many of the tumour cells grouped in acini about a central lumen, and especially such acini just beneath the stretched, overlying intestinal mucosa showed the characteristic fine infra-nuclear granules reacting positively.

Appendix from a woman aged twenty showing two argentaffin cells stained by Baker's acid-haematein method. ($\times 1,000$)

Sections of this tumour stained by Gomori's⁶ hexamine-silver nitrate method showed that these granules in morphologically similar cells gave the characteristic argentaffin reaction. Although in this latter case the test was not performed strictly according to Baker's specifications, in that sections were cut from gelatin blocks of tissue fixed for several weeks instead of six hours in formal-calcium before chroming, it affords strong presumptive evidence that the characteristic alkaline silver-reducing granules very often seen in the cells of argentaffin tumours also contain a phospholipine.

Photoelectric Spectrophotometry of Planetary Nebulae

THE electron temperature of a planetary nebula can be determined from the relative intensities of the N_1 and N_2 lines of [OIII] at $\lambda\lambda 5,007, 4,959$, and the 'auroral' type transition at $\lambda 4,363$, provided the target areas for collisional excitation are known¹.

The N_1 and N_2 radiations are usually very much stronger than $\lambda 4,363$. The photographic measurement of the intensity of $\lambda 4,363$ with respect to $H\gamma$ and $H\beta$ is not difficult; but photographic photometry is not

well suited to the measurement of the ratio, R , of the intensity of $N_1 + N_2$ to that of $H\beta$. This is because the ratio is often large, the sensitivity of the emulsion is changing rapidly in the spectral region involved, and the nebular images in the light of hydrogen and [OIII] often show structural differences. Accordingly, a check upon the photographic determinations of this ratio is very much to be desired.

Between May and August 1953 we obtained some photoelectric measures of the ratio R in a number of planetary nebulae using the 24-36-in. Schmidt telescope of the Warner and Swasey Observatory. The objective prism provided a spectral image of each nebula at the focus (97"/mm. and 275 Å./mm. at $H\beta$). An RCA type LP21 photomultiplier tube with associated equipment¹ measured directly the total light intensity in the various spectral images. Details of the procedure for eliminating the effects of overlapping images, spectral sensitivity of the cell, atmospheric extinction, and the stellar continuum will be published elsewhere.

For the five planetaries listed in the first column of Table 1 numerical values for the ratio, R , are given in the second column. The probable errors of R are listed in the third column, and the number of runs over the spectrum of the nebula, n , are given in the fourth. The more precise photoelectric results confirm the accuracy of Aller's photographic measures² given in the last column.

Table 1

NGC	R photoelectric	Probable error	n	R photographic
6,543	8.07	0.14	10	8.1
6,826	9.8	0.2	3	10.7
6,573	15.75	0.13	11	13.9
7,027	20	1	1	18.7
7,662	20.0	1.4	4	21.2

The photoelectric observations provide additional information which is very difficult to obtain by other methods, namely, the intensity of the emission lines in terms of the energy in the continuum of the central star. Results for two planetaries are given in Table 2. For each, the number in the second column is the intensity of N_1 and N_2 combined in terms of the energy per angstrom in the stellar continuum at 45,007.

Table 2

NGC	$N_1 + N_2/\text{cont.}$	Probable error	n
6,826	2,300	140	3
7,662	1,500	60	4

We wish to thank Mr. L. H. Aller for directing our attention to this problem from the observational point of view.

Fermi's Thermodynamic Theory of the Production of Pions

Fermi's¹ statistical thermodynamic theory of the generation of pions in collisions of high-energy nucleons has stimulated considerable discussion of the problem. The theory is in reasonably good agreement with observation; but the theory is not free, as Fermi himself and others² have pointed out, from conceptual difficulties. However, the purpose of the present note is to show that in the usual derivation¹ for the number of pions produced on Fermi's theory, the contribution of the pions in the lowest energy-state is not adequately taken into account. In fact, because of the Lorentz-contraction of the volume (in which pions are produced) the usual estimate of the total number of pions produced has an appreciable error. In the absence of the Lorentz-contraction the error would be entirely negligible.

Let us consider the sum (in the usual notation):

$$N_1 = \sum_i \frac{1}{e^{\alpha_i - 1}}, \quad \beta = 1/kT. \quad (1)$$

Let N stand for the integral

$$N = \frac{4\pi g \Omega}{(2\pi\hbar)^3} \int_0^\infty \frac{p^2 dp}{e^{\alpha} - 1} = \frac{4\pi g \Omega}{(2\pi\hbar)^3} 2! \frac{\zeta(3)}{\beta^3}, \quad (2)$$

where Ω is the volume of the assembly and g the weight factor for the pions ($g = 3$).

If we write

$$N_1 = N + N_0, \quad (3)$$

then it follows that

$$N_0 = \alpha g kT / \mu c^2, \quad (4)$$

where α is a numerical factor of the order unity. If W is the total energy of the colliding nucleons in the co-ordinate system (called O -system) in which the total momentum is zero, we have, on substituting for (kT) in terms of W :

$$\frac{N_0}{N} = \frac{\alpha [9\pi \zeta(4)]^{1/3} \left(\frac{g\mu}{M}\right)^{1/3}}{2\zeta(3)} \frac{1}{(\gamma f)^{1/3}}, \quad (5)$$

where M is nucleon rest mass, $\gamma = W/Mc^2$, and f is defined by

$$f = \Omega / \bar{\Omega}_0, \quad \bar{\Omega}_0 = \frac{4\pi}{3} (\hbar/\mu c)^3. \quad (6)$$

When $f \sim 1$, $\frac{N_0}{N} \rightarrow 0$ for large γ . However, in Fermi's

theory the volume available in the O -system for production of pions is not $\bar{\Omega}_0$, but the Lorentz-contracted volume $2\bar{\Omega}_0/\gamma$. Hence, we have

$$\frac{N_0}{N} = \alpha \frac{[9\pi \zeta(4)]^{1/3} \left(\frac{g\mu}{2M}\right)^{1/3}}{2\zeta(3)} \sim 0.54 \quad (\text{for } \alpha = \frac{1}{2}). \quad (7)$$

Thus the number N_0 is of the same order as N , and hence Fermi's expression (equation (2)) seriously underestimates the total number of pions produced. In the laboratory system the N_0 pions will form a narrow jet moving along the direction of the incident nucleon, each pion having an energy $\gamma\mu c^2/2$.

Thermoelectric Power of Cold-worked Copper at Low Temperature

THE influence of cold-working on the thermoelectric power has been measured by a number of workers¹. At room temperature we carried out measurements on copper and silver wires. For a certain amount of cold-working it is found that the relative increase of the absolute thermoelectric power is greater than the relative increase of the resistivity. These results do not agree with the theoretical prediction of T. Hirone and K. Adachi².

So far as we know, no measurements have been carried out at low temperatures.

We measured the thermoelectric force between a wire, drawn at room temperature, and an annealed wire as a function of the temperature of the hot junction. The cold junction was always kept at liquid air temperature (83° K.) (Fig. 1).

Each curve reaches a minimum at a certain temperature which is dependent on the amount of cold-working. At the minimum the thermoelectric power (in 10^{-4} V. per deg. C.) is zero; it is positive above but negative below the corresponding temperature. So the absolute thermoelectric power increases above and decreases below the temperature mentioned.

Fig. 2 shows the temperature of the minimum, shown in Fig. 1, as a function of the percentage reduction of the area of the wire. In the same temperature-range we found cold-worked silver wires always had a positive thermoelectric power relative to annealed material.

Fig. 1. The thermoelectric force plotted against the temperature of the hot junction for various percentage reductions by drawing. The cold junction is continually kept at 83° K. The thermoelectric force is always measured with respect to the same annealed copper wire.

Fig. 2. The temperature of the minimum of a curve of Fig. 1 plotted against the corresponding percentage reduction of the area of the wire.

As usual we call a metal *A* positive with respect to a metal *B* if at the cold-junction the (positive) current flows from *A* to *B*. So far as we know the results for copper do not agree with any theory on the thermoelectric power.

Measurement of the Hall Coefficient of α - and β -Brass

THE measurements described herewith were undertaken in order to find out whether any pronounced change in the Hall coefficient takes place when passing from α - to β -brass.

The well-known method employing d.c. was used, and the specimens were cut from thin sheets of brass. Small blocks of the materials were produced from thin copper wire and small pieces of zinc by melting in vacuum in a quartz tube, and the sheets were then produced by rolling from these small blocks. (The specimen of 52 per cent copper was milled down from a cast block.) The rolling was carried out at room temperature; but due to work-hardening after a number of operations, it was found necessary to anneal the work once by heating in an inert atmosphere (nitrogen). The specimens were then cut out in rectangular pieces about 48 mm. by 17 mm. The thickness, measured directly, varied from 0.0778 ± 0.0004 mm. to 0.156 ± 0.0005 mm. The d.c. was applied to the specimens through two circular contacts (2 mm. diam.) placed symmetrically with a distance between centres of 40 mm. To exclude errors due to a fixed current direction, the polarity was reversed now and then.

A correction¹ for the short-circuiting of the Hall field by the contacts for the primary current has

Crosses: Present measurements; lengths of vertical and horizontal branches of the crosses indicate the standard deviations.
 ●, measurements by H. H. Hall

been introduced in the evaluation of the Hall coefficient.

The magnetic field was provided by an electro-magnet and the field-strength was found to vary by not more than 0.3 per cent over the area of the sample. The alteration in the Hall potential, brought about by reversing this magnetic field while the current was kept constant, was measured by means of a highly sensitive galvanometer. A potentiometer was connected to two points (with a distance between them of about 4 mm.) of one of the long edges of the specimen. The galvanometer was connected to the slide and to a point on the other edge of the sample, just opposite the potentiometer. The slide was then moved until no potential difference appeared by reversal of the current in absence of the magnetic field². To minimize thermoelectric forces in this arrangement, all connecting wires as well as the potentiometer wire were taken from the same length of copper wire.

The results of the investigation are plotted in the accompanying diagram, showing the Hall coefficient as a function of the content of copper in the brass. Each point is the result of forty measurements made at 4-8 different d.c. currents (up to 27 amp.), but all with the same magnetic induction (0.646 V./m.² = 6,460 gauss), and the standard deviations are indicated in the diagram. Four points from measurements made by E. H. Hall in 1885³ are also plotted. The composition of the brass was determined by the weight of copper and zinc before melting them together. On account of the annealing the homogeneity of the specimens was high and was found to be satisfactory by chemical analysis of different parts of the brass samples. Thanks are due to Mr. J. Rathlev, for making the analyses.

Down to about 65 per cent copper the alloy can be considered to be pure α -brass. At 52 per cent copper it can be considered to be pure β -brass. It appears that the sign of the Hall coefficient is unaffected by the change from α - to β -brass, in opposition to what might be expected from the theory of H. Jones⁴ for the phase boundaries in binary alloys.

I wish to thank Prof. T. Bjerge and Prof. H. Højgaard Jensen for their interest in this work and for much valuable advice.

Direct-Current Corona

It has previously been reported that the corona in a point-plane gap to which is applied a steady d.c. potential (positive point, negative plane) consists of a series of short-duration pulses^{1,2}, and this had also been observed by me. The results of English¹, who used a photomultiplier to study the light emitted by the corona, show that this light is emitted in the form of pulses of total duration of approximately 6×10^{-8} sec. with "a plateau which gives the impression of two overlapping peaks".

Recently, I have studied the corona for the above-mentioned experimental conditions, using an oscillograph and amplifiers which enable random pulses of a few tens of micro-amperes amplitude and of duration of the order of 10 msec. to be displayed. The current flowing in the gap due to the corona was investigated by inserting a resistor in series with the earthy point and displaying the volt-drop produced across this resistor, after amplification, on the oscillograph. Since the capacitance of the pointed electrode may be made very much smaller than that of the plane electrode, the time-constant associated with the measuring equipment may, by this means, be reduced to a minimum.

For a gap-length of approximately 3 cm. between a platinum wire of 0.005 cm. diameter and an aluminium plane in air at atmospheric pressure, 'noise' is observed from about 9 or 10 kV. upwards. This noise is less than 10 μ amp. mean amplitude and is similar to that seen, for example, on a normal linear sweep. It is unidirectional, increases in amplitude with increasing voltage and vanishes with removal of the voltage from the gap. The measurement by a micro-ammeter of the d.c. current flowing in the pointed electrode gives a value which agrees with the mean level of the noise as seen on the oscillograph, within the limits imposed by the difficulty of calibrating an amplifier with a gain of approximately 30,000 and a band-width of around 100 Mc./sec.

Increase of the applied voltage to about 15 kV. causes the appearance of the pulses which are shown in the accompanying figure (A). The amplitude of these pulses is 2-300 μ amp. peak and their repetition-rate is low, but increases with increasing voltage. Due to the short duration and low repetition-rates of these pulses, their contribution to the current in the gap, as measured by a micro-ammeter, is negligible.

At about 19 kV., the pulse shape is as shown in B, from which it will be seen that most of the pulses are the same as in A; but that a few of them develop a 'plateau' on the back of the pulse. In some cases, this plateau is ended by a fall to zero, but in others the current rises until the amplifiers are saturated. The duration of the plateau is variable.

Reduction of the amplifier gain enables the pulse shape of this rising current to be observed, and this is shown in *C*. The pulses have a peak amplitude of approximately 20 m.amp. and a duration of approximately 0.3 μsec. These pulses are therefore similar in duration to that of the impulse corona²⁻⁴, although the duration of the front of the d.c. corona pulses

appears to be larger than that of the impulse corona.

A further increase of the applied voltage causes secondary pulses to occur on the backs of some of the pulses shown in *C*, and the resultant pulse shape is shown in *D*. At this voltage, occasional spark breakdown may occur.

Visual observation of the gap at the stage when the pulses shown in *C* are present shows that luminosity appears to extend across the whole gap, being confined to a channel of small diameter near the point and spreading out in a fan-shape nearer the plane, and being enhanced by contact with this electrode.

The velocity of propagation of the luminosity has been measured with the aid of a photomultiplier technique⁵, and I find that this luminosity moves from the point to the plane at a constant velocity of approximately 4×10^7 cm./sec. Within the limited range available for investigation to date, this velocity is independent of the gap length. The amount of light emitted by the luminosity as it crosses the gap remains approximately constant, and the extension of the luminosity in the direction of motion, at any instant, appears to be small compared with the gap length.

The small 'bump' on the top of the wave-form shown in *C* appears to coincide with the arrival of the luminosity at the plane.

The duration of the pulses shown in *C* appears to be affected by a change in either the gas pressure or the composition of the gas—a mixture of nitrogen and oxygen.

It should be pointed out that the above phenomena occur without the introduction of any external irradiation, and may therefore be considered to be self-sustaining.

The interpretation of the phenomena described is not yet clear, except possibly in the case of the 'noise'. This cannot be considered as a 'shot-effect' since a current of 8 amp. is required to give an r.m.s. shot-noise current of 10 μamp. for a band-width of 100 Mc./sec. It would therefore appear that the 'noise' is caused by electron avalanches, individual avalanches being subject to statistical variations in the number of component electrons and therefore in

the current produced, and the number of avalanches at any time also being statistically variable.

The amplitudes, durations and repetition-rates of the pulses shown above are such that the measurement of the current in the gap by a d.c. meter is unlikely to give an indication of the existence of the pulses, and therefore any analysis of the breakdown mechanism made solely from such a measurement will probably be false.

Abnormalities of Stored Seed

SEEDS of a variety of plants have been stored in unsealed air, sealed air, and carbon dioxide. All have been kept at laboratory temperature for five years. In all cases unsealed seed has deteriorated more rapidly than sealed seed. Furthermore, CO₂-sealed seed has generally given better germination than seeds stored in sealed air. In two varieties of lettuce the original yield of mature plants from sealed seed has been maintained while the plants grown from unsealed seed have a diminished yield (Table 1). Lettuce and onion seeds have been selected for a cytological study because these showed marked differences in deterioration and were suitable material technically.

Chromosomal aberrations in *Crepis* and *Allium* raised from old seed have been reported^{1,2}. We have likewise found gross abnormalities in old lettuce and onion seed; but as with germination, these effects are influenced by the type of storage (see Table 1).

Primary roots were fixed approximately one day after germination, that is, at the end of the period of elongation and at the time that the cells were undergoing their first mitoses. The total anaphase cells were scored from at least five roots from each of the treatments to assess chromosome breakage and mitotic activity. The results are summarized in Figs. 1 and 2.

Examination of metaphase cells in lettuce has revealed that all the breakage is of the chromosome type, that is, it is occurring in the early resting stage before the time of chromosome reproduction, giving

Table 1. PERCENTAGE GERMINATION AND YIELD

		Lettuce variety						Onion
		White Heart (cm)	May Queen (cabbage)	Continuity (cabbage)	Archie King (cabbage)	Black Seeded Bath (cm)	Bedfordshire Champion	
Storage	Unsealed	24 (4)	0	66 (8)	11	20 (3)	2	
	Sealed air	86 (17)	12	91 (8)	65	92 (19)	11	
	Sealed CO ₂	96 (18)	66	96 (9)	56	93 (17)	33	
	Control	97	90	91	94	86	76	

Figures in brackets are mean yields of mature plants in ounces

dicentric but no chromatid interchanges. At anaphase the resulting bridges and fragments are readily observed (Fig. 3).

The lettuce varieties tested show a differing effect of the treatments, and this difference is reflected in breakage, mitotic activity and germination. Although varietal differences occur, the general trend shows a sharp decrease in chromosome abnormalities at high germination values and a corresponding rise in mitotic activity. The onion results, however, differ markedly from the lettuce in revealing a low incidence of breakage at all levels of germination. This shows that in the case of onion, at least, a decrease in germination is not necessarily determined or followed by an increase in the frequency of abnormal cells.

It has been stated that decreased germination and increased chromosome breakage are parallel effects of ageing². The present results clearly show that ageing alone is not responsible for these changes as storage conditions can overcome the effects of age.

Three varieties of lettuce under discussion were grown to maturity in 1953. The diminished yield in White Heart and Black Seeded Bath grown from unsealed seed (as shown in Table 1) was probably due to a reduction in root formation consequent upon the high proportion of abnormal cells present in the primary root.

Fig. 1. Relationship between germination and mean number of anaphases per primary root. (The latter used as an index of mitotic activity.) Lettuce varieties: White Heart, May Queen, Continuity, Arctic King and Black Seeded Bath numbered 1-5 respectively. Onion 6. Fig. 2. Relationship between germination and abnormal anaphases in primary root. Key same as Fig. 1

Fig. 3. Abnormal anaphase in a primary root cell of White Heart lettuce 24 hr. after germination of 5-year-old seed. Shows criss-cross separation of a dicentric chromosome and two pairs of acrocentric chromatids. Foulgen squash preparation. ($\times 2,800$)

cells is low they can be readily replaced by active division of normal cells, as has probably occurred in the variety Continuity.

Each of the three groups of plants of Black Seeded Bath grown from sealed and unsealed seed was fertile and produced viable seed. When sown after a short dormancy period each batch of seeds underwent normal germination and the primary roots showed normal mitotic activity with no chromosome abnormality. The gross rearrangements in the parental seedlings were not transmitted to the next generation, but small viable rearrangements may have been perpetuated.

These results show that gaseous exchange plays a large part in the metabolic processes of the resting seed and, in the case of sealed air and carbon dioxide, has counteracted to some extent the effects of age. The effects of ageing upon seeds must, however, be recognized as complex, and the production of cytological abnormalities to be a consequence rather than the initial cause of seed deterioration.

Time of Death of Sex-linked Lethals of Different Origins in *Drosophila melanogaster*

PREVIOUSLY it had been found that the great majority of ultra-violet-induced lethal mutations involving no detectable chromosome changes cause the death of the individual carrying the mutation shortly before or after emergence of the larva from the egg case, or shortly before or after the transformation of the larva into the pupa, while a few caused death just before or after eclosion from the pupa case¹. As an extension of this study it was planned to examine the immature stages of lethals of other origins in order to determine the times when they exerted their deleterious effects.

	Embryonic stages			Larval instars			Pupal stages			Totals
	Early	Middle	Late	1st	2nd	3rd	Early	Middle	Late	
1 Spontaneous lethals	0	0	1	18	0	9	8	0	4	35
2 X-ray-induced lethals	0	0	1	20	0	4	8	0	6	39
3 Ultra-violet-induced lethals (ref. 1)	0	0	7	27	0	9	9	0	3	55

Two groups of lethals were investigated:

(1) Sex-linked lethals which had arisen spontaneously in the female.

(2) Sex-linked lethals which had been induced by irradiation of mature spermatozoa with an X-ray dose of 700 r.

Methods for collecting and examining the immature stages of the lethal-bearing individuals have been described elsewhere¹.

The distribution of lethality is given in the accompanying table.

Two third-instar lethals have been found in the spontaneous group which exhibit melanotic tumours at the time of death, and these are being further investigated.

The clustering of mortality is similar to that found previously for the ultra-violet-induced lethals. Hadorn has found a somewhat similar distribution of the time of death of fifty-nine non-allelic autosomal lethal mutations which arose spontaneously or had been induced by the chemicals phenol or sulphuraphen². The X-ray-induced lethals used, all of which were studied cytologically, were found to involve no detectable chromosomal aberrations³ and the spontaneous lethals, although not examined cytologically, probably also represent point mutations. Thus the finding of a similar distribution as to the time when these lethals and those produced by ultra-violet radiation exert their detrimental effects lends further support to our earlier interpretation that lethal point mutations exert their killing effect usually during the stages when many physiological functions new to the individual come into active operation for the first time in its life.

This work was supported by a grant from the U.S. Atomic Energy Commission.

I wish to express my appreciation to Dr. H. J. Muller for his interest and many helpful suggestions during the course of this work.

Heat Therapy of Virus-Infected Raspberries

Of the various techniques claimed to effect cure of virus-infected plants, only those involving heat treatments of plant material have given consistent results. Warm water treatments and exposure to high air temperature have been used by a number of workers to free plants from certain virus diseases, including raspberries infected with *Rubus stunt*¹.

The purpose of this communication is to describe a method that has been used successfully for freeing raspberries from certain aphid-transmitted viruses

which differ from *Rubus stunt*. Material for treatment was drawn from virus-tested stocks of Norfolk Giant infected with leaf mottle virus, Malling Jewel with a mixture of viruses including leaf spot, and Malling Promise and Lloyd George (New Zealand stock) each infected with unidentified latent viruses^{2,3}. Dipping whole canes and root cuttings in water at temperatures ranging from 35° C. to 50° C. for periods up to two hours failed to effect a cure. But in 1952 virus-free plants of Lloyd George and Malling Jewel were obtained by subjecting growing plants to an air temperature of 32° C. for periods of one to four weeks. After the treatments terminated, the plants were grafted to healthy plants of *Rubus henryi*, a species which is hypersensitive to infection with any of the known raspberry viruses⁴. Absence of symptoms in *R. henryi* is at present assumed to imply freedom from virus in the plant tested. The plants surviving from the first trials have twice been so tested and are still virus-free.

Since then the technique has been improved, and virus-free plants of all four varieties listed above have been obtained. Experiments were begun in June 1953 and are still continuing. Strongly growing plants in 5-in. pots were first defoliated and then peaked in trays of damp peat moss and transferred to a square box of side 3 ft., electrically heated and thermostatically controlled to $\pm 0.5^\circ$ C. Humidity was maintained by daily watering of the pots and peat, and light was supplied for seventeen hours daily by a 400-W. mercury-vapour lamp fitted over the roof of the box. Large plants were pruned to accommodate them more readily into the box. The apparatus was kept in a room not subject to marked temperature fluctuations.

During the first experiment the air temperature was maintained at 32° C. and successive batches of four plants of each of the varieties Norfolk Giant, Lloyd George, Malling Promise and Malling Jewel were exposed for 8, 10, 12, 16 and 20 days. All the plants survived. From the three lots of sixteen plants treated for 8, 10 and 12 days respectively, three, eight and five virus-free plants have so far been recovered; the results of the longer treatments are not yet known. In a second experiment the temperature was raised to 35° C. and the plants, then approaching dormancy, were cut down to about 6 in. After a few days treatment, young shoots appeared, and these continued to grow normally during the experiment. Again, all the plants survived for periods of up to 16 days; but the treatments terminated too late in the season for graft testing to be carried out.

No cures were effected in one earlier trial where plants were exposed for four days at 32° C., and the results so far suggest that exposures longer than eight days are necessary to give a high proportion of cures. The data are insufficient to establish whether there are differences in the resistance to heat treatment among the viruses present in the raspberry plants used, but this is being investigated.

Provided that heat-treated raspberry plants are not altered in other and more detrimental ways than in being freed from virus infection, the potentialities

of this technique for the ready production and maintenance of virus-free oenas are obvious.

Cuticles of Erupted Teeth

It is generally agreed that Nasmyth's membrane, which is present on the enamel surface of recently erupted teeth, is composed of an outer cellular and an inner structureless layer, and that shortly after eruption the cells are lost due to degeneration and masticatory trauma. Whether or not the inner structureless layer remains on the surface is a matter of controversy, but it may be inferred from recent papers that it does remain throughout life¹⁻³. This, however, is difficult to envisage in view of the findings of Scott *et al.*⁴ and Scott⁵, who have demonstrated the wear which takes place continually on the enamel surface of erupted teeth, although it is true that these authors do speak of a 'cuticle'.

On the other hand, Manly⁶, Vallotton⁷ and Atkinson⁸ have reported the formation of an amorphous membranous deposit on the enamel surface of erupted teeth. This suggests the possibility of confusion between two membranes of differing origin.

In agreement with Atkinson's findings an amorphous cuticle, resembling in appearance the inner structureless layer of Nasmyth's membrane, has been recovered from areas of enamel attrition as well as from the remaining enamel surface. However, on close examination two differences were observed. First, only the inner layer of Nasmyth's membrane exhibits interference phenomena, and secondly, this layer is marked by outcrops of the enamel prism ends grouped in lines typical of the unworn enamel surface, whereas the cuticle present on older erupted teeth is marked either faintly or not at all. Furthermore, the two membranes differ chemically. The cuticle of erupted teeth is more stable in strong acid at room temperature, and at boiling point it forms 'humin'. This, together with the positive reactions obtained with protein and carbohydrate tests, may indicate that the cuticle contains both these substances in combination. The nature of this combination is indicated by metachromatic staining with toluidine blue and by a positive periodic acid-Schiff reaction, suggesting that the cuticle may contain a mucoprotein. Lipoid is also demonstrable using sudan B.

In consequence of these observations, a series of experiments was carried out using the crown of a 'normal' caries-free tooth extracted from an adult. After removal of the cuticle by immersion in acid the tooth was fitted to a partial denture. This denture was worn in the mouth for periods varying from 7 to 63 days. At the end of each period a cuticle, which in all respects resembled the naturally occurring structure on the enamel of adult erupted teeth, was removed from the crown surface. It is interesting to note that this occurred in spite of the fact that some features of a vital tooth, such as those concerned with enamel permeability, were absent. Atkinson and Prophet⁸ suggested that substances from the saliva might be involved in the formation of 'crack lamellae'.

In the present investigation the naturally occurring cuticle is found to be connected with such lamellae, which show the same properties chemically (in contrast with developmental lamellae obtained from unerupted teeth).

From these observations it appears evident that what in the past has been identified on adult erupted teeth as the inner structureless layer of Nasmyth's membrane has, in fact, been a cuticle formed, and capable of re-formation, after eruption. Bacteria are not found to be constituents of the cuticle.

Divergence in Helical Polypeptide Chains and in Phyllotaxis

In the α -form of synthetic polypeptide chains (poly-L-alanine, poly- γ -methyl-L-glutamate) divergences of the individual amino-acid residues of 5/18, 8/29 or 13/47 corresponding to helix periods of 27 Å, 43 Å, or 70.4 Å, are discussed^{1,2}. The numerators of these figures remind one of the divergences of phyllotaxis, where 5/13, 8/21 and 13/34 are members of the

$$\text{phyllotaxis sequence } \frac{1}{2} \frac{1}{3} \frac{2}{5} \frac{3}{8} \frac{5}{13} \frac{8}{21} \frac{13}{34} \dots$$

In this sequence the numerator and the denominator of every member is the sum of those of the two preceding members. Since this regularity applies also to the divergences discussed for the α -polypeptide helices, an extrapolation to hypothetical lower members of a similar sequence is possible. As a result the following

$$\text{helix sequence } \left(\frac{1}{3} \frac{1}{4} \frac{2}{7} \frac{3}{11} \right) \frac{5}{18} \frac{8}{29} \frac{13}{47} \dots$$

is obtained. It is possible that higher members of this sequence might have a practical significance for polypeptide helices with long-range periods higher than 70.4 Å. The lower extrapolated members, between brackets, have probably no real meaning; they are only mentioned to show that the discussed divergences are members of a very striking sequence, comparable to that in phyllotaxis.

The similarity is certainly due to the same geometrical cause, that is, as dense as possible an arrangement of identical objects along a helix. In the case of phyllotaxis these objects are the protuberances of the young leaves on the growing point in a bud, and in that of the polypeptide helices the amino-acid residues in the crystal lattice.

Wednesday, March 31

BRITISH INSTITUTION OF RADIO ENGINEERS, LONDON SECTION (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6.30 p.m.—Mr. R. Hanbury Brown: "Radio Astronomy".

ROYAL INSTITUTE OF CHEMISTRY (joint meeting with the CHEMICAL POLYTECHNIC SOCIETY, at Chelsea Polytechnic, Madres Road, London, S.W.3), at 7 p.m.—Mr. W. M. Lewis: "Science in Criminal Investigation".

Wednesday, March 31—Friday, April 2

CHEMICAL SOCIETY (at the University, Manchester)—Anniversary Meetings.

Wednesday, March 31

10.30 a.m.—Symposium on "Dynamic Stereochemistry".

Thursday, April 1

11.30 a.m.—Prof. H. J. Emeléus, F.R.S.: "Organometallic Compounds containing Fluorocarbon Radicals" (Liversidge Lecture).

Friday, April 2

11 a.m.—Presidential Address by Prof. O. K. Ingold, F.R.S.

Thursday, April 1

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. D. W. Henderson: "The Work of the Microbiological Research Department".

AGRIC (at the Royal Society of Arts, 8 John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Dr. Richard Offer: "History of the Inter-University Council for Higher Education in the Colonies".

INSTITUTE OF METALS, LONDON LOCAL SECTION (at 4 Grosvenor Gardens, London, S.W.1), at 6 p.m.—Annual General Meeting, followed by Discussion on "The Brittle Fracture of Metals".

Thursday, April 1—Monday, April 5

BRITISH PSYCHOLOGICAL SOCIETY (at the University, Nottingham).—Annual Conference.

Friday, April 2

SOCIETY OF CHEMICAL INDUSTRY, FINE CHEMICALS GROUP (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Annual General Meeting; at 7.30 p.m.—Dr. D. S. Morris: "Chloramphenicol".

ROYAL INSTITUTE (at 21 Albemarle Street, London, W.1), at 9 p.m.—The Right Hon. Lord Rothschild, F.R.S.: "Spermatozoa".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN AGRICULTURAL BOTANY—The Secretary of University Court, The University, Glasgow (March 31).

ASSISTANT LECTURER (with a degree in agriculture or equivalent qualification, and sound experience in practical work, and, if possible, in teaching) in AGRICULTURE, at the Cumberland and Westmorland Farm School, Newton Riggs, near Penrith—The Director of Education, 5 Portland Square, Carlisle (April 3).

LECTURER IN ORGANIC CHEMISTRY, a LECTURER IN PHYSICAL AND INORGANIC CHEMISTRY, an ASSISTANT (Grade B) IN PHYSICS, an ASSISTANT (Grade B) IN BIOLOGY, and an ASSISTANT (Grade B) IN CHEMISTRY, at Birkhead Technical College—The Director of Education, Education Offices, 63 Hamilton Square, Birkhead (April 3).

ENGINEERS (3) (with first- or second-class honours engineering degree (civil or mechanical)) in the Department of Scientific and Industrial Research, Forest Products Research Laboratory, Prince

Harborough, Bucks, for investigations on timber strength, wood sawing and machining—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.99/54A (April 3).

LECTURER (with good university degree or equivalent, and with considerable teaching and industrial or research experience) in AIRCRAFT STRUCTURES, to teach subject to final B.Sc. and H.N.O. standard—The Principal, Royal Aircraft Establishment Technical College, Farnborough, Hants (April 3).

MATHEMATICIAN (with at least H.S.C. (science) or equivalent) at the Ministry of Supply Guided Weapons Establishment, Aberporth, South Wales, to undertake responsibility for film reading and computation section, including interpretation of records, and investigation of new and modified analysis techniques—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.58/54A (April 3).

SCIENTIFIC OFFICER or SENIOR SCIENTIFIC OFFICER (with first- or second-class honours degree or equivalent qualification, in physics, chemistry or metallurgy), for development work on carbon for nuclear reactors, involving structural studies of porous solids—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Berkshire, quoting 2/103/70 (April 3).

EXPERIMENTAL OFFICER, Grade III (with degree or diploma in engineering, or equivalent qualifications, and several years experience in wind tunnel investigations related to aircraft or missile development) in the Department of Supply, Aeronautical Research Laboratories, Fishermen's Bend, Victoria, Australia, to carry out wind tunnel investigations related to the development of new aircraft and missile types—The Senior Representative (AP.11), Department of Supply, Australia House, Strand, London, W.C.2 (April 5).

PRINCIPAL SCIENTIFIC OFFICER (Supersonic Theory) (with a degree of high standard in mathematics, and extensive experience of theoretical work in supersonic aerodynamics and ability to direct the work of others) in THE HIGH SPEED AERODYNAMICS LABORATORY, Department of Supply, Salisbury, South Australia, to initiate and be responsible for research, especially of a mathematical nature, in supersonic and transonic flow; and to exercise supervision over the work of other scientific staff and of a small computing "pool"—The Senior Representative (A.P.10), Department of Supply, Australia House, Strand, London, W.C.2 (April 5).

PHYSICIST or CHEMIST, Principal Scientific Officer grade (with first- or second-class honours degree or equivalent in physics or chemistry, and considerable research and development experience in the field of high polymers, particularly natural and synthetic rubbers) at the London Headquarters of the Ministry of Supply, for duties which will include initiation and progressing of research and development work on rubbers for Service purposes, and advice to Service Departments on technical applications of rubber—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.183/54A (April 10).

SENIOR LECTURER IN GEOGRAPHY at the Fourth Bay College, Sierra Leone (University of Durham)—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (April 12).

PHYSICAL CHEMIST (with a first- or second-class honours degree in physical chemistry or equivalent qualifications, and preferably with previous experience of chemistry of plastics and polymers) at the National Coal Board, Stoke Orchard, near Cheltenham, for work on chemical and physical changes in coal during carbonization—The National Coal Board, Central Research Establishment, Stoke Orchard, near Cheltenham, Glos, quoting TT/751 (April 15).

BRITISH COKE RESEARCH ASSOCIATION FELLOW (honours graduate in chemistry, physics, or applied science related to fuel technology), to work on the physical chemistry of carbon, under the direction of the Professor of Physical Chemistry—The Registrar, King's College, Newcastle-upon-Tyne (April 19).

ASSISTANT LECTURER (3) in PSYCHOLOGY—The Registrar, The University, Manchester (April 21).

SENIOR LECTURER IN PHYSICS—The Registrar, The University, Sheffield (April 21).

ASSISTANT LECTURER IN THE DEPARTMENT OF BIOCHEMISTRY—The Secretary, University College London, Gower Street, London, W.C.1 (April 22).

LECTURER, Grade II (with a degree in metallurgy, engineering or related science), in INDUSTRIAL METALLURGY—The Registrar, The University, Edgbaston, Birmingham 15 (April 30).

LECTURER or ASSISTANT LECTURER in ORGANIC CHEMISTRY at the University College of North Staffordshire—The Registrar, The College, Keele, Staffs (April 30).

MYCOLOGIST in THE PLANT PATHOLOGY DEPARTMENT—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (April 30).

RESEARCH FELLOW IN PURE SCIENCE at the University of Durham—The Secretary, University of Durham, 38 North Bailey, Durham (April 30).

SENIOR and JUNIOR RESEARCH FELLOWS (with first- or second-class honours degree in an appropriate subject, and able to show evidence of a very high standard of ability in research) in Government Scientific Establishments, for research into subjects of importance to H.M. Government—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4300/54 (April 30).

UNIVERSITY LECTURERS or UNIVERSITY DEMONSTRATORS at THE FACULTY OF ENGINEERING, University of Cambridge—The Secretary of the Appointments Committee, Engineering Laboratory, Cambridge (April 30).

ASSISTANT LECTURER IN PURE MATHEMATICS—The Registrar, University College, Hull (May 1).

RESEARCH STUDENTSHIP in CHEMICAL ENGINEERING tenable in the Department of Chemical Engineering, University of Cambridge—The Secretary, Department of Chemical Engineering, Tennis Court Road, Cambridge (May 1).

LECTURER in SOCIAL ANTHROPOLOGY—The Registrar, King's College, Newcastle-upon-Tyne (May 1).

PROFESSOR OF PHYSICS at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, May 1).

SENIOR RESEARCH OFFICERS (3) (preferably with specialized post-graduate training in a branch of science applied to agriculture) to take charge of sugar cane research in the main ecological divisions of the sugar cane area—The Director of Research, Sugar Research Department, Mandeville, Jamaica, British West Indies (May 7).

LINCOLN IN PHYSICS at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, May 10).

RESEARCH RESEARCH FELLOWS (3) (graduates of British universities) for research in chemistry or physics—The Registrar, The University, Sheffield (June 1).

LINCOLN (with a good honours degree in botany and research experience, preferably in genetics) in BOTANY, at the Imperial College of Tropical Agriculture, Trinidad, British West Indies—The Secretary, The Imperial College of Tropical Agriculture, 40 Norfolk Street, Strand, London, W.C.2 (June 30).

ASSISTANT LINCOLN, Grade B (with a good honours degree in physics or electrical engineering, and some research, industrial or teaching experience) in THE DEPARTMENT OF APPLIED PHYSICS AND ELECTRICAL ENGINEERING, College of Technology and Commerce, Cardiff—The Director of Education, City Hall, Cardiff.

BIOCHEMIST (with at least a good second-class honours degree, with appropriate postgraduate experience) at the West African Fisheries Research Institute, Sierra Leone—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting ODL197/194/01.

GEOLOGIST (with second-class honours degree, Division 1, in geology, or equivalent) in the Gold Coast Civil Service, for geological mapping, investigation of mineral deposits and water supplies, etc.—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting ODL105/13/07.

ORGANIC CHEMIST for fundamental research on the chemistry of cellulose and its derivatives, a CHEMIST (with a leaning towards physical and/or analytical chemistry) for fundamental research in cellulose chemistry, a PHYSICAL CHEMIST to study the degree of polymerization of macromolecular substances, with ultra-centrifuge, etc., a CHEMIST or PHYSICIST (with a knowledge of X-ray crystallography) for research on the structure of textile fibres, a CHEMIST (with experience in infra-red spectroscopic techniques) for research on the structure of textile fibres and on the mechanism of dyeing, a CHEMIST for fundamental and technical research on the bleaching of textiles, and a CHEMIST for fundamental and technical research on the chemical finishing of textiles, with the British Cotton Industry Research Association—Dr. F. C. Toy, Director of Research, Shirley Institute, Didbury, Manchester 20.

PHYSICISTS (with good honours degree, and with some experience or training in research, not necessarily textile research) for work on textile problems—The Secretary, British Rayon Research Association, Barton Dock Road, Urnston, Manchester.

PRINCIPAL SCIENTIFIC OFFICERS (with at least a second-class honours degree in physics or engineering, and with three years post-graduate research experience, and a knowledge of fluid dynamics) at the Department of Atomic Energy, Copenhagen, near Chester, as project leaders on engineering physics problems connected with gaseous diffusion plant and power reactors—The Department of Atomic Energy, Industrial Group Headquarters, Risley, Warrington, quoting 568.

PROTOZOOLOGIST (with a medical or veterinary degree or diploma registrable in the United Kingdom, and two years postgraduate research experience, and a sound knowledge of protozoology) at the East Africa Tsetse and Trypanosomiasis Research and Reclamation Organisation, to undertake research in the human and animal trypanosomiasis—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting ODL196/196/01.

SINGER

Micromanipulators

Singer (High-power) Micromanipulators are suitable for use under magnifications of from $\times 100$ to $\times 1,000$ diameters plus, as described by Barer and Saunders-Singer in the *Quarterly Journal of Microscopical Science*, Vol. 89, pp. 439-447, December, 1948.

Singer Microdissectors (Low-power Micromanipulators) are suitable for use under magnifications of from 1 to $\times 200$ diameters and are described by Barer and Saunders-Singer in the *Journal of Scientific Instruments*, Vol. 28, pp. 65-68, March 1951.

BECK BINOCULAR EYEPIECE ATTACHMENT

Angular Model

This attachment enables the monocular microscope to be instantly converted into the binocular type. It can be used with any power object glass and has all the qualities of the binocular bodies which are built into the microscope. The inclined angle is a great convenience for those who work with the microscope for prolonged periods.

Catalogue giving full details forwarded on application.

Optical Fused Quartz

Transparent fused quartz can be supplied for optical purposes as blanks for plates, lenses, prisms, etc., or as finished optical elements up to the highest degree of optical finish and freedom from strain.

It is manufactured in various grades, thus providing a suitable quality for each class of work ranging from the most exacting uses in ultra-violet optical determinations to ordinary work in the near ultra-violet and infra-red regions. We shall be pleased to recommend a suitable quality for your particular application.

MSE 'magnum' centrifuge

5 litres * speeds up to 5,000 r.p.m.

range of accessories * automatic timer

A perfect general purpose medium to large centrifuge. It will accommodate a swing-out head 500-ml. bottles and a large range of other swing-out and basket type heads with all usual buckets, and multiple carriers. All controls are grouped on a panel which can be hinged right down for access to the entire electrical installation.

April 8-13. Stand No. 81

"Speedivac" miniature Vapour Pumps, though 'handy' in size, are remarkable outside performers. The addition of one of these small oil or mercury vapour pumps to your existing rotary pump system brings the immediate advantages and unlimited scope of a high vacuum system—an invaluable aid to industrial research and pilot experiment effected on a reduced scale.

for better vacuum service... **W. EDWARDS**

RECORDING PHOTO-DENSITOMETER
Model 2 SR**

Based on a design by Latner, Molyneux & Rose
(J. Lab. Clin. Med. : 1954, 43, 157)

Patents
applied for

With this instrument, the quantitative analysis of strips obtained by Electrophoresis can be performed accurately and simply. Model 2 SR has been designed for use with reflected light, eliminating the necessity of rendering the strip translucent. As the reflection from the strip is balanced against an optical wedge and because of the single photocell - double beam principle used, a high degree of accuracy is achieved. Model 2 SR is particularly useful when working with low concentrations. A novel scale adjustment enables a reasonable deflection to be obtained with dye intensities barely visible by eye. Model 2 ST is available for Transmitted Light Operation. Because of its accuracy, the instrument has wide research applications. Due to the speed of this semi-automatic instrument, it is also ideal for routine work; up to 20 strips an hour can be analysed by almost unskilled personnel.

PEPTONES AND HYDROLYSATES *for Microbiological Culture Media*

Difco peptones and hydrolysates are prepared to meet the diversified nutritional and biochemical requirements of microorganisms. A single peptone cannot provide the essential nitrogenous nutrients for all cultural and metabolic processes. Difco peptones and hydrolysates have been developed to meet the various requirements for microbiological procedures including growth, preparation of toxin and vaccines, and for the study of microbial metabolism.

THE INDEPENDENT RESEARCH INSTITUTION

THE major and wider interest of Dr. Vannevar Bush's report for 1952-53 as president of the Carnegie Institution of Washington lies in his review of the position and opportunities of the privately endowed research institution to-day, particularly in view of the concern so freely expressed in the United States and elsewhere as to the growing dependence of fundamental research on government support. Dr. Bush begins his report with an appreciation of the particular opportunities of the Carnegie Institution itself, before turning to discuss the position of the independent research institution in general. His observations are an important contribution to a discussion which was provoked afresh by the analysis of government expenditure on research in the United States carried out by the National Science Foundation, and they have a close bearing on the future activities of such bodies in Great Britain as the Nuffield Foundation and the Carnegie United Kingdom Trust.

Dr. Bush is impressed by the opportunities which confront the Carnegie Institution, provided national conditions permit it to operate effectively. He sees the Institution's work on the genetics of lower organisms and the earlier phases of life processes as fundamental to the future use by man of lower organisms for food production, to separation of raw materials from the sea and the synthesis of complex organic compounds for industry or for physical welfare: "There is evident opportunity for another fifty years of exacting endeavour in elaborating a constantly widening set of concepts". So, too, he believes that out of the Institution's studies of the ionosphere, of terrestrial magnetism and of geophysics, may come improved communications, new sources of materials and a fuller understanding of man and his environment.

Turning to the general position, Dr. Bush points out that the view that the day of the independent research institution is ended and that in future fundamental research belongs to the universities with heavy subsidies from government implies two criticisms. First, it implies that the research institution is isolated and that the interchange and cross-fertilization of a university community is essential now that disciplines are becoming more intimately interlinked. Second, it implies that fundamental research and the education of brilliant students should be closely related, and that the research institution is prone to ingrowth and stagnation in the absence of the continued impact of young minds. Dr. Bush admits that these are cogent points of which the research institution must take account. He does not admit, however, that the criticism is necessarily valid. These are dangers to be watched rather than reasons for abandoning the research institution. Isolation is a matter of attitude rather than of geography, and it can characterize a university department as well as an independent institution. A research department far from universities may

become a national or even a world intellectual centre in its field, where those intimate interchanges between masters occur which are often the seeds of progress. Dr. Bush's remarks bear pertinently on the question of academic interchange and the wisdom of doing all that is possible to foster schemes for academic interchange now being operated.

Nor is formal education, which is not the business of the research institution, the only means of contact with youth. Dr. Bush maintains that if a research institution allows itself to become old in its ways the fault is its own, and especially, he suggests, in its methods of selecting and treating its staff. If it is careful to expose itself constantly to the influence of young minds, to select its recruits not simply for their mental ability but also for their capacity to blend into a scientific community, and if its younger members are at once given the opportunity of participating effectively in its programmes, its group discussions and plans, the research institution will go far towards maintaining its vigour and avoiding the danger of rigidity and narrowness to which a community of scientists alone is liable.

This problem is inherent in all research organizations, and Dr. Bush is emphasizing much that was well put in the Barlow report on scientific staff ten years ago. His essential point is that the research institution is quite as well able to create the conditions which will attract outstanding men and give full play to their creative ability as any other form of research organization; and apart from this, he believes that the independent institution has advantages which more than offset any dangers of rigidity or ossification. Outstanding achievement in fundamental research is above all a matter of locating the individual of genius and supporting him liberally as he pursues his own way. Dr. Bush's philosophy is fully in line with that expounded by Mr. Raymond B. Foedick on behalf of the Rockefeller Foundation and Mr. Chester I. Barnard for the National Science Foundation.

It is, however, not to the utterly lone genius, incapable of working with others, that scientific advance owes everything; we must also consider those whose brilliant creative skill is combined with the human attributes that make them welcome in a community of their peers, so that their full creative contribution is seen not merely in their own direct results but also in terms of men as well. Dr. Bush believes that the independent research institution, free from the distractions of teaching, is even better placed than a university department to provide the climate in which such individuals can function to the best of advantage. He believes also that the research institution, with its tightly knit groups, is also better equipped than the university department for locating genius before it has matured and established a reputation. Young men of promise are best picked by men in the same field, subject to checks first by senior colleagues, and then, as in the Carnegie Institution of Washington, by such officers as the president and trustees, who are concerned to see that high standards are maintained and due diligence emphasized in the quest for talent.

A new young scientist of great creative ability is best developed, in Dr. Bush's opinion, by incorporation in a group consisting largely of men of that character, whose selection of novices, rotation and further selection is under the leadership of a scientist possessing the sound judgment in the selection of men which is a primary attribute of a successful director of research.

All this can, of course, be done in a university department, though so far as fundamental research is concerned, Dr. Bush thinks, less successfully. These are his reasons for believing that, provided the research institution is adequately endowed, fundamental research can be carried on more fruitfully in it than anywhere else; and on this question of endowment Dr. Bush is highly critical of recent trends in the finance of research in the United States. He points out that the sponsoring of fundamental research by the Government has not hitherto increased significantly the volume of fundamental research. More important, it has not, by sponsoring, created new centres of research or secured the permanent expansion of existing centres. Moreover, the great foundations have turned away from endowment grants and distributed their funds mainly on a project basis.

Although this distribution, as is clear from such reports as those of the Rockefeller Foundation and the Nuffield Foundation, has been directed largely towards what are, in the judgment of their trustees, the growing points, in accordance with the view for which Lord Beveridge argued so cogently in his report on "Voluntary Action", Dr. Bush believes that, by keeping the selection of actual projects in their own hands, the Foundations have hindered the full expansion of fundamental research. He believes they have missed an opportunity. When the Government began to increase strongly its support of scientific research, they should have maintained the balance by increasing their own support of fundamental research, and particularly by creating and endowing new independent institutions where it was most likely to prosper.

Dr. Bush admits that something has been done; but he maintains nevertheless that the scope for fundamental research has expanded far more than the means for its furtherance. In general, independent foundations have not tackled the problem of extending fundamental scientific research in the United States, nor is there any great indication that they will do so.

So far as the United States are concerned, Dr. Bush's remarks have to be considered in the light of the opinion freely expressed in that country that the level of fundamental research is far below what is required to enable it to make contributions to the advancement of science, as distinct from technology, commensurate with its greater resources. The National Science Foundation's recent inquiry showed that in 1951-52 the total funds available to non-profit institutions for research and development were 338 million dollars, compared with the Federal Government's appropriation of 2,217 million dollars; and although the latter figure is estimated at 2,074 million dollars for the fiscal year 1953-54, the

resources of non-profit institutions are unlikely to exceed the previous 15 per cent of the Federal funds available for research and development. Moreover, from the latter funds expenditure on fundamental research is of the order of 120 million dollars, or some six per cent of the total, and this expenditure tends to increase less proportionately than that on applied research and development. Further, of the funds going to non-profit institutions, only about 20 per cent was for basic research, the remainder being for applied research and development. Even in medical research there has been a similar trend, Federal funds providing a major source of support—roughly 76 million dollars out of 181 million dollars in 1951, compared with 60 million dollars from industry. The Commission on Financing Higher Education in the United States estimates that out of 222 million dollars expended by higher education institutions on organized research in 1950, about 60 per cent was on contract research for the Federal Government.

American opinion is thus disturbed, both that this large Federal contribution is not big enough for the amount of fundamental research that is desirable, and that it represents too high a proportion of the funds available for the research institutions. This latter concern is increased because, as the Commission on Financing Higher Education in the United States suggests, much of the Federal support goes for purposes ill-related to those which the research institution is primarily concerned to further. Apart from the danger of distortion inherent in this position, concern has been expressed, for example, by Mr. R. D. Reid, of the Office of Naval Research, that the effects on individual freedom and initiative may be adverse. Although the Office of Naval Research seeks to administer its research programmes and funds so as to stimulate creative work and the increase of fundamental knowledge, Mr. Reid views the trend towards Federal support with uneasiness. He distrusts reliance for funds upon any single agency, even the National Science Foundation, for support of basic research even in the medical sciences. Finance is not the sole or even the most important requirement, and several agencies, with their differing points of view, their various needs and different groups of advisers, offer a greater safeguard against uniformity, and assurance that due consideration will be given to research projects in entirely new fields—to the potential growing points—of which bodies such as the Rockefeller and Nuffield Foundations and the Carnegie Institution are rightly mindful.

The Office of Naval Research carries responsibilities which in Great Britain largely fall on the Department of Scientific and Industrial Research or the Medical Research Council, and this warning as to the limitations of administration deserves to be noted. Moreover, while accepting the necessity of group research or team-work, Mr. Reid reminds us that the important discoveries are usually the result of the intellectual adventures of talented individuals, and his comment that in his personal experience some enforced frugality has stimulated productivity is parallel to an observation of Sir Ernest Barker in his recent book. Sir

Ernest wonders whether we do not think too much about equipment and accommodation. They matter, but perhaps not as much as we think. Sir Ernest's experience that poor accommodation is often a spur to good education is, of course, not a justification for ill-equipped laboratories, but endorsement of the truth of Rutherford's remark: "We haven't any money; we've got to think".

Still more recently, President H. W. Dodds, of Princeton University, has discussed the dangers and limitations of project research in a statement on university research policy published in the *American Scientist* (42, 128; 1954). President Dodds recognizes that the team-work usually demanded in sponsored research when it is good can make for cross-fertilization and mental stimulation, while the external discipline laid upon the leader and his team to see that the trust is honoured is also an advantage. None the less, there is a danger of diminishing returns, and like Mr. Reid, Dr. Dodds notes the danger of decreasing self-reliance and of over-planning and regimentation. A university, he insists, must never, in accepting projects, swerve from its obligation to advance fundamental knowledge, but above all Dr. Dodds is concerned that the imposition of secrecy in connexion with sponsored projects contravenes the prompt and free pooling of knowledge by which all science advances.

Any barrier to the free trade in ideas throttles the process of discovery, and Dr. Dodds suggests that three principles should determine the acceptance of any sponsored research project by a university. The sponsored undertaking should be related to the fundamental long-range programmes of the faculty concerned. Second, the undertaking must not interfere with the university's duty to maintain and improve its own resources and facilities for the support of its own programmes; and third, the university must exercise the same diligence and wisdom in the utilization of its own resources as it does in respect of grants which it accepts from outside for sponsored research.

Apart, however, from the dangers which may beset the research institution if it does not exercise great discrimination in the acceptance of sponsored projects, there is a further difficulty, to which Dr. C. P. Richter has directed attention in an article, "Free Research versus Design Research" (*Science*, 112, 91; 1953). Dr. Bush in his report to the trustees of the Carnegie Institution recognizes the importance of the Institution retaining the power to select its own projects in the light of the collective wisdom of the research group. Mr. Richter hammers home the point that unless the individual has reasonable freedom, we do not get the best out of him. Funds for research, he argues convincingly, should be given with as few strings attached as possible. Experimental design should not be mistaken for ideas, and it is the man rather than the project who should be backed, at least so far as fundamental research is concerned. These points are just as applicable in Great Britain as in the United States, and those concerned with the allocation of funds for research should always have them in mind.

ATOMIC ENERGY IN GREAT BRITAIN AND THE UNITED STATES

Britain's Atomic Factories

The Story of Atomic Energy Production in Britain. By K. E. B. Jay. Pp. ix+100+16 plates. (London: H.M. Stationery Office, 1954.) 5s. net.

Report on the Atom

What You Should Know About Atomic Energy. By Gordon Dean. Pp. 288+16 plates. (London: Eyre and Spottiswoode (Publishers), Ltd., 1954.) 16s. net.

THE nearly simultaneous appearance of these two books on the subject of atomic energy is in a sense a real landmark in the history of the subject. Both are written with inside knowledge of the spectacular developments made in recent years in this rapidly growing field. One is concerned with British progress and the other with American. The report by Mr. K. E. B. Jay is more restricted in its scope and, indeed, he does not stray far from the chosen subject of factories at any time. On the other hand, Mr. Gordon Dean gives his attention to nearly all the questions that are involved in any comprehensive study of the atomic energy programme, including the use of weapons. Yet the aims of the authors are very similar. Throughout they are anxious to explain the methods of the responsible bodies, the Ministry of Supply in Britain and the United States Atomic Energy Commission, and they perform their tasks with clarity and as much detail as necessary.

Both writers achieve an unusually high standard of lucidity in expounding what is largely a complicated scientific and technological subject. There is some little suggestion of the expert turned reporter in Mr. Jay's work and what one might call the reverse in Mr. Dean's. But the degree of success is such as to leave one with a feeling of regret that such instances do not occur more frequently. It is obvious that a law training is not lost in scientific fields.

The bulk of each book is concerned with a highly complex scientific and engineering project, and in spite of their notable success it is still true to say that the educated layman will find much that is difficult to digest. All the material is interesting and even stimulating to the careful reader; but the books are meant for serious study, and application is essential to extract anything like their full value. Mr. Jay's account shows clearly a desire to provide the scientific basis for the various processes described, but he is wise in providing the exposition of the underlying physical principles in the form of an appendix. This allows him to proceed without seriously overloading the average reader at any point. Mr. Dean succeeds very admirably in this same respect by virtue of his ready ability to draw neat analogies from more familiar fields of experience.

The specialist will find a great deal to interest him in these books. The comprehensive sweep of the authors over fields involving physics, chemistry and engineering serves to clarify the principal trends in the whole project. In spite of unprecedentedly firm control of publication, there has been a great number of papers from the various laboratories involved, and these books help in relating many of these specialized publications. Both books start with prospecting for ore and go as far as the pile for energy production

or the door of the weapons factory. Mr. Dean side-steps actual weapon production; but he has many interesting and timely points to discuss concerning tests, stockpiling, strategy and other related topics. Regarding tests, many scientists will envy electricians who can earn 800 dollars a week, even if the circumstances are exceptional. In addition to handling weapons, Mr. Dean considers security and the Russian effort; here he shows a reasonable middle-of-the-road approach which will be favoured by many and which can provoke very few.

In one respect both writers, through no fault of their own, leave the reviewer rather unhappy. Much of their effort is expended in demonstrating how well both programmes have been handled. This appears to be a rather barren effort as there are no standards of comparison, or very few, in this field. Both are national efforts, and security prohibits any estimate of the cost of an atom bomb or even an ounce of plutonium, say. It is somewhat like the situation when the management insists that it has cleverly handled affairs, but nevertheless refuses to give any financial statement on the operation. It is difficult for the shareholders to join the eulogy no matter how sympathetic they feel towards the claims of the personnel. Apart from this question of what might be termed efficiency, there is left with the reader a very real sense of difficulty in estimating how long it will be before piles supply useful energy on a commercial basis.

There is a compactness and neatness in the British programme as described which contrasts rather strongly with the apparently more haphazard and empirical approach in the United States. Yet somehow one is impressed with the feeling that the latter method would probably achieve real results very quickly if it was directed mainly along the line of peaceful applications. The main contrast, indeed, in the two countries is not in technological matters, although differences do appear here (as, for example, in the processing of ores), but rather in its organization. The American scheme of awarding contracts to industrial companies, mostly of major standing, on a cost plus nominal fee basis does not have a real counterpart in Britain. Although many well-based objections can be made to the American system, and these are fully and frankly voiced by Mr. Dean, one is yet aware of the enormous benefits that can accrue when it proves successful. One feels that the more tightly governed British effort could result in a severe handicapping of the major firms in the international race towards successful tackling of the many original scientific and technological problems created in the widespread application of atomic energy in a peace-time economy. Names such as Du Pont, General Electric, Westinghouse and Union Carbide and Carbon appear throughout the American report, and in several instances the whole problem is left to these concerns. The difficulty of ensuring that full use is made of the nation's skill is aggravated by the fact that the British effort was delayed by the transfer of the whole of the British personnel to the United States during the War. Thus the American manufacturer had a big start in the new field, and his progress in the construction of ship reactors (submarine) is perhaps an especially noteworthy example of this.

The above is merely one of the many issues that will occur to the thoughtful reader of these two authoritative and excellent accounts of the work in atomic energy. All non-specialists are indebted to

each of the writers for bringing under one cover so much of a subject which is of vital concern to all. Both books can be very highly recommended. They are in no sense in competition with each other—they are, in fact, complementary. They are excellently produced and cheap for books of their type. It is unfortunate that Mr. Jay's work is not produced with a more durable cover. S. C. CURBAN

PHILOSOPHICAL ANALYSIS OF 'OBJECTIVE' PROBABILITY IN SCIENCE

Scientific Explanation

A Study of the Function of Theory, Probability and Law in Science. By Richard Bevan Braithwaite. (Based upon the Tarnier Lectures, 1946.) Pp. xii + 376. (Cambridge: At the University Press, 1953.) 40s. net.

THE eleven chapters of this book are intended to examine (or re-examine ?) the logical features of all sciences. The term 'science' is understood to mean a hierarchical deductive system in which the lowest-level generalizations from the observed facts are deduced from more-general higher-level hypotheses. This very general level of discussion is maintained in Chapters 1-4 (introduction; scientific deductive systems and their representations; the status of theoretical terms in science; models for scientific theories, their use and misuse). Also, the same general tone is characteristic of the last four chapters (the justification of induction; laws of Nature and causality; causal and teleological explanation; explanation of scientific laws). The middle of the book, composed of three chapters (statistical hypotheses, probability statements and class-ratio arithmetic; the meaning of probability statements within a scientific system; the choice between statistical hypotheses), is much more specific than the rest and deals with the gnoseological questions related to modern theories of probability and statistics and, more particularly, to the applications of these disciplines in experimental sciences.

In his preface Mr. R. B. Braithwaite states that, "if I were asked what there is that is original in this book, I should mention specifically the accounts of probability as used within a science (Chapters V and VI) of the relation between scientific theories and 'models' of them (Chapter IV), and of teleological explanation (Chapter X)". With respect to the other parts of the book, the originality of the author is limited to exposition. No doubt, because of my personal inclination, the most interesting parts of the book appear to be Chapters 5-7, which are given to probability and statistics. Since the appearance of J. M. Keynes's "Treatise on Probability" (1921) and through the writings of Sir Harold Jeffreys, the philosophical literature on probability has mostly been based on the view that the term probability reflects in some way the intensity of belief of an individual in a given proposition. For this reason, the particular theories are sometimes called 'subjective' theories of probability. On the other hand, beginning roughly with the last years of the nineteenth century (Karl Pearson), a tremendous amount of work has been done on the development of the mathematical machinery and on its applications to the various branches of empirical science

in which an essential part is played by relative frequency. This 'relative frequency' is attached to the appearance of various 'events' in repeated 'trials' either going on by themselves or performed by man. The idealized relative frequency became labelled with the same term 'probability'. Since the assertion that probability (understood as an idealized relative frequency) of a given event has a specified value p may be verified experimentally, the relevant theory is sometimes called the 'objective' theory of probability.

Perhaps because of the enormous field of applications (physics, astronomy, biology in general and heredity in particular, social sciences and experimentation) that kept the scholars busy with immediate specific problems, the existing philosophical literature concerned with 'objective' probability appears to be much less rich than that dealing with the 'subjective' probability. The honour of initiating the philosophical study of objective probability seems to belong to R. von Mises ("Wahrscheinlichkeit, Statistik und Wahrheit", Vienna, 1928). To my knowledge, the present book represents the next (after von Mises) serious effort to analyse the position and the meaning of objective probability in the body of modern science.

While the author's attitude towards probability in science seems to coincide with that of von Mises, there are very considerable differences in the developments. First, Mr. Braithwaite refuses to adopt von Mises's definition of probability as the limit of relative frequency. The definition adopted, based on the so-called 'class ratios', is essentially the same as the now classical definition of Kolmogoroff. (Here, however, somewhat to my surprise, the author is reluctant to deal with infinite sets and measure.) Furthermore, at the time when von Mises wrote his book the basic concepts of the modern statistical theory were much less clear than they are now, and this is reflected in von Mises's writings. Mr. Braithwaite has benefited from his proximity to the Cambridge Statistical Laboratory and, with the acknowledged co-operation of F. J. Anscombe, has mastered the young mathematical discipline. As a result, his book appears to contain the first presentation of the principles of mathematical statistics intended for a non-technical reader. This presentation is concise and at the same time quite inclusive, from the theory of testing statistical hypotheses, through estimation, to the general theory of statistical decision functions. Also, and this is quite an achievement, Mr. Braithwaite's presentation of the theory is devoid of the various misty mysticisms so frequently encountered in the many not quite technical books written by statisticians. In fact, they (the statisticians) will do well to read Mr. Braithwaite's book. Some of them will probably disagree with him on a number of points, but the process of disagreeing will be instructive. In general, the book is likely to be interesting to everyone anxious to attain a unified outlook on science.

One bibliographical remark seems in order. The concept of loss function, $L(h_1, h_2)$, that represents the financial loss to the statistician who accepts the hypothesis h_1 when, in fact, an alternative hypothesis h_2 happens to be true, is frequently attributed to Wald. There is some justification for this because in modern times Wald was the first to make extensive use of this concept, combining it with the 'minimax' idea. However, it is interesting that the loss function appears in the writings of Laplace in the form of

'detriment' that one will suffer when using an estimate $\hat{\theta}$ of a parameter the true value of which is θ . Laplace chose a particular form of the function to represent the 'detriment', namely, $|\hat{\theta} - \theta|$. Later on, the same problem was considered by Gauss, who noticed that much simplicity is gained by assuming the alternative form of the detriment $L(\hat{\theta}, \theta) = (\hat{\theta} - \theta)^2$. Incidentally, the adoption of this form of loss function initiated the theory of least squares and caused the contemporary preoccupation with the mean square error of an estimate, which is exactly the expectation of the detriment. In more modern times, the concept of the loss function or of detriment appears frequently in the writings of F. J. Edgeworth, but then, for some reason, became entirely forgotten. In 1933 the concept was rediscovered by E. S. Pearson and myself (*Proc. Camb. Phil. Soc.*, 29; 1933), and combined with the notion of what is now known as the minimax policy. However, after formulating the idea, we did nothing with it. The next rediscovery of the idea was due to Wald, who used it to the fullest extent and on it built his remarkable general theory of statistical decision functions. JERRY NEYMAN

HIGH-SPEED FLUID FLOW

Modern Developments In Fluid Dynamics

High Speed Flow. Composed under the aegis of the Fluid Motion Sub-Committee of the Aeronautical Research Council. Edited by L. Howarth, with the assistance of H. B. Squire and the late C. N. H. Lock. (The Oxford Engineering Science Series.) Vol. 1: pp. xvi+476+9 plates. Vol. 2: pp. viii+400+17 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1953.) 84s. net the set.

THE publication of these two volumes on aerodynamic phenomena as affected by the compressibility of the air will satisfy a long-felt want by many workers in the aeronautical field. Like their predecessors, these volumes appear under the aegis of the Fluid Motion Sub-Committee of the Aeronautical Research Council, but the editor is Prof. L. Howarth in place of Prof. S. Goldstein, to whom the work is dedicated.

The original volumes dealt only with the problems of fluid dynamics at speeds sufficiently low for the density of the fluid to be considered a constant. The very rapid progress of flight into transonic and supersonic regions has produced a great demand for aerodynamic data at such high speeds, where the effects of variations of density, viscosity and temperature can no longer be neglected and indeed play a dominant part in determining the nature of the flow. These two volumes set out to supply this need as far as is possible at the present time when many of the problems involved are far from completely solved. The editor and his collaborators are to be congratulated on the production of a fine work, especially as they must have felt themselves greatly hampered by the lack, in very many cases, of sufficiently extensive experimental data to enable them to assess the validity of approximations necessarily made in the theoretical treatment of the subject.

It can truly be said that in this field theory has outstripped experiment and that the great need of the moment is a systematic body of experimental

data such as has been amassed during the past thirty years or so for the case of low-speed flight. There are two reasons for this lack: in the first place, problems of high-speed flight have been under intensive consideration for a comparatively short time; and in the second place, the equipment needed for their adequate experimental study is much more elaborate and expensive than that which sufficed for low-speed problems.

Dealing first with the theoretical side, which is the special province of the first volume, the field of investigation divides itself roughly into two parts. There is first the range of speeds from that at which compressibility begins to matter to that of sound, and this range is particularly difficult from the theoretical point of view when the field of flow comprises both subsonic and supersonic velocities and is characterized by shock waves of limited extent springing from the surface of the body considered. Secondly, there is the true supersonic range in which velocities are everywhere supersonic, so that the mathematician is no longer confronted by equations of both elliptic and hyperbolic type in the same field of flow. There are not yet, in fact, any complete analytical solutions of flow problems in which limited shock waves exist, but only in the cases where the speed is below that at which shock waves form or above that at which the flow is completely supersonic. Nevertheless, it is possible to throw some light on the intervening region by approximate methods.

After a general introduction and description of high-speed flow, the equations of flow in gases are elaborated, and in succeeding chapters the implications of these laws of flow are traced. The method of characteristics is described, and the properties of shock and blast waves examined. The hodograph method is treated at some length, and there is an interesting chapter on approximate methods, some of which have been of great use, despite their limitations, in giving the aeronautical engineer a basis for supersonic design. Problems of unsteady flow are next considered and complete the review of theoretical methods as applied to flow in an inviscid fluid. The last chapter, on boundary layers, shows how the methods previously developed for incompressible flow have been extended to the compressible case, and also contains some account of the interaction of shock waves and boundary layers, a subject as yet far from being completely understood.

The second volume, apart from its last chapter, deals mainly with the experimental study of high-speed flow. An account is given of the apparatus and methods that have been devised for such research, including force measurements, determination of pressure distribution, and visualization of flow by shadowgraph, schlieren and interferometer methods. Two chapters follow in which some of the available results are given on aerofoils and cylinders, and on bodies of revolution, illustrated by numerous diagrams and some excellent flow photographs. The discussion on bodies of revolution is confined mainly to spin-stabilized projectiles, and it is pointed out, quite rightly, that the study of projectiles took workers into the supersonic field even before flight was regarded as a serious possibility. It is an interesting thought that two apparently widely separated investigations, external ballistics and the aerodynamics of flight, have now merged together, and each can help the other in no small measure. The last chapter of the second volume deals with the

problem of heat transfer at high speeds. This is a matter of very great importance, and one that will become even more important as flight speeds increase, for it seems likely that the ultimate speed of man-carrying aircraft will be set by the thermal problems involved. Theoretical methods of dealing with heat transfer are considered, and their predictions, compared with experimental results, indicate that knowledge is in a fairly satisfactory state, considering the complexity of the problem.

The present volumes, like their predecessors, are provided with very copious references to other work on the subjects discussed. Recent progress in the theoretical and experimental study of high-speed fluid dynamics has been very extensive indeed, because of its obvious and vital importance in the development of air defence, and it is quite impossible to treat more than the broad outlines of the subject even in two fairly large volumes. The reader who wishes to look more closely into any particular part of the subject will find the references of great value.

While much of the theoretical matter is fundamental and will stand permanently, there seems little doubt that the present intensive experimental programme, in Britain and elsewhere, will very soon enable the subject to be treated far more fully. For the moment, the present volumes form probably the most complete account of the subject yet published.

ERNEST F. RILEY

MASS SPECTROMETRY

Modern Mass Spectrometry

By Dr. G. P. Barnard. (Physics in Industry Series.) Pp. 326. (London: Institute of Physics, 1953.) 50s.

MANY still think of the mass spectrometer as a highly academic instrument, details of which have to be remembered only long enough to pass examinations in physics, whereas, as Dr. G. P. Barnard's book shows, it is now a powerful tool which has successfully invaded the world of industrial and biological research. The last five chapters of the book are, in fact, devoted to a discussion of some of the problems tackled by mass spectrometers. The longest of these chapters concerns only one application—the analysis of hydrocarbon mixtures; and here the actual position is well reflected, for it is in the oil-refining industry that mass spectrometers are now most used. The following chapter is devoted to applications in chemistry; and another is concerned with the use of mass spectrometers in biology. The latter contains also much useful material of a general nature on the techniques peculiar to stable-isotope tracer work with deuterium, carbon-13, nitrogen-15 and oxygen-18 respectively. Other shorter chapters are concerned with geology, physics, nuclear chemistry and engineering.

It should not be thought, however, that the mass spectrometer is not itself discussed in detail, for more than half the book is devoted to its general theory and design. Dr. Barnard's work on gaseous ion sources and their errors is well known, and his chapter on ion sources should therefore be approached with some respect. The space allotted to sources suitable for solid samples, however, is small; largely, of course, because little work has been published about them. This is regrettable, for in spite of their in-

conveniences and inefficiency the use of a source of this type could often, one feels, short-circuit a routine chemical operation involving small quantities of gas—always a laborious affair.

It is in those sections of the book dealing with more fundamental matters that a few obscurities appear. Thus, in the section dealing with circular motion of a charged particle in a uniform magnetic field, we find the statement "there is no linear acceleration but a constant angular acceleration". Again, electrostatic units are used here, but later, without warning, a formula appears which is based on Gaussian units; and on p. 73 we read of the "normal to a point". Such minor matters, however, are few in number and do not detract appreciably from the value of the book as a whole.

One cannot conclude a review of this book without mentioning the very full list of references, containing nearly five hundred entries—a most useful appendix. For its size, the book is expensive; this is doubtless because the publishers cannot expect to sell it in really large numbers, for its material is somewhat specialized. Yet for this very reason the Institute of Physics and the author are to be congratulated on their enterprise, for the book will be of great utility to many research workers in helping them to appreciate the possibilities—and limitations—of mass spectrometers.

D. F. BRACHER

"STRASBURGER'S TEXT-BOOK"

Lehrbuch der Botanik für Hochschulen

Begründet von E. Strasburger, F. Noll, H. Schenck und A. F. W. Schimper. 26. Neu bearbeitete Auflage. Bearbeitet von Prof. Hans Fitting, Prof. Walter Schmumacher, Prof. Richard Harder und Prof. Frantz Firbas. Pp. xii+661. (Stuttgart: Gustav Fischer Verlag, 1954.) 28 D. marks.

A FUTURE historian of botanical literature, surveying both sides of the Atlantic, may well regard the present period as the heyday of text-books, certainly of those that aim at instruction at the 'intermediate' level; the reflective, contemporary teacher may easily find himself wondering how long the large (and expensive) text-book will continue to hold its own in schools and universities. The volume being considered here is, of course, the one that has been long and widely known in its English translation as "Strasburger's Text-book". In parenthesis, we may perhaps note that the sixth and last English edition, translated by Prof. W. H. Lang and published by Messrs. Macmillan in 1930, was based on the seventeenth German edition. Now, in this, the twenty-sixth German edition, we may say that not only does the soul go marching on, but also the body, at least in its general framework, has remained relatively unchanged, although it has been appropriately brought up to date within the limitations of that framework. On the title-page acknowledgment is still made to its original authors of 1884—Strasburger and his colleagues—and in the prefatorial matter the comprehensive authorship of the several sections during the past seventy years is set out.

As in the earlier editions, the book begins with morphology, which is subdivided into cytology, histology and organography, with a short section dealing with the theory of descent and the origin of adaptations. In the second section, physiology is considered under metabolism, development (actually

changes of form) and movement, genetics and the effect of environmental factors being considered as subsections of the physiology of development. The third section, which deals with the systematic arrangement of plants from Schizophyta to Monocotyledonae, retains the general form of earlier editions, though within some subdivisions and classes there has been extensive rearrangement. Some of these new taxonomic arrangements differ considerably from those in earlier editions and also from those in what may be described as recent standard works. The Algae afford one example of this, the retention of the concept of Pteridophyta another. As the materials in this section are necessarily very condensed, and as we have by no means come to a stage of finality in the resolution of the problems of taxonomy, it would be quite impossible in a short review to enter into detail on this aspect. The most evident single new addition to the original publication is the inclusion, since the twentieth edition, of a section on plant geography.

The reviewer of a broad conspectus of the subject such as this naturally tends to test it by scrutinizing in detail those sections with which he himself is most familiar. On the basis of this criterion it can be said that this new edition has been comprehensively modernized—review literature as recent as 1952 is cited in some of the sections—and that the student can gain access to representative recent and contemporary data and ideas, if not in the unavoidably condensed text, then from the judicious selection of literature cited at the end of the book. We have, in short, the qualities and limitations of the old substantial "Strasburger", with some of its coloured illustrations still retained, and still affording a comprehensive and representative survey of scientific botany in its many branches. O. W. WARDLAW

PROGRESS IN PHYSIOLOGY, 1952-53

Annual Review of Physiology

Victor E. Hall (Editor), Jefferson M. Crismon and Arthur C. Giese (Associated Editors). Vol. 14, 1952; pp. x+589. Vol. 15, 1953; pp. x+558. (Stanford, Calif.: Annual Reviews, Inc.; London: H. K. Lewis and Co., Ltd., 1952-53.) 6 dollars each vol.

EVERYONE with any interest in physiology must be deeply grateful to those who produce the "Annual Review". The lists of contents of the volumes for 1952 and 1953 promise good reading, with an attractive mixture of young men and famous names. The editorial policy in choosing fields, the balance kept between basic physico-chemical aspects and the physiology of highly organized systems are admirable. The guidance to those preparing review articles for these volumes and the hope that the reviews will reflect the personal views of the author are obviously enlightened; and yet there is scarcely more than one article in each volume which one reads with pleasure as well as profit.

There are a few minor blemishes. It should be easy to remove more of the errors in English grammar of the European contributors, and one could wish that time permitted the correction of comments which seem to be unintentionally ambiguous. The real difficulty lies in the degree of responsibility which any one author feels able to accept for passing over

nonsense in silence, praising discriminatingly, criticizing even widely accepted views, and on occasion proposing some new framework to carry the facts available.

Selection of papers to be mentioned cannot be easy. One author plaintively remarks that three thousand articles on the thyroid have appeared during the past two years. While the "Quarterly Cumulative Index" and the newcomer, the "Current List of Medical Literature of the U.S. Armed Forces Medical Library", are available, there is no need for "Annual Review" to catalogue. I feel that even more vigorous selection of titles is unlikely to leave many gems in obscurity, and that reviews with more than two hundred references are overlaid and indigestible. Other evasions of duty include the habit of saying that "the results of this author are not consistent with current concepts". Surely this is simply sitting on the fence. To say that *A* says white but 'in contrast' *B* says black, usually means that the reviewer has not bothered to see if *A* and *B* are working in comparable conditions.

Here and there reviewers can be heard grinding their private axes; but with such a glorious opportunity the temptation must be difficult to resist. One practice which should be sternly suppressed by the editor is Prof. J. F. Fulton's habit of publishing extracts from letters from authors on their unpublished experimental results. Clearly the reviewer has little chance of judging for himself the significance of work reported in letters, and he is poaching on the preserves of the reviewer for 1955. Fulton includes an attack on cybernetics on the grounds that it offers nothing conceptually new and has spread unhappy confusion among students. I feel that cerebellar tremor should be considered from the point of view of stable and unstable feedback mechanisms, instead of being ascribed, as it is now, to irregularities of muscle action. The present view seems both unhappy and confused.

Two most enjoyable papers were those of Alan Burton on "Peripheral Circulation" in the 1953 volume and J. R. Robinson and R. A. McCance on "Water Metabolism" in the 1952 volume. As a former physicist and for the past twenty years a biophysicist, Burton is well placed to castigate pretentious nonsense in physical aspects of physiology. His comments on "pulmonary capillary pressure", on the calculation of the area of stenosed mitral valve and on "coupled elastic rams" are well deserved. It is not surprising that while dealing such swinging blows he is occasionally unkind and even unfair. More of such vigorous criticism would have a salutary effect on authors.

The paper by Robinson and McCance is chiefly memorable for an expansion of ideas put forward previously by Robinson. They state the current view that all cells are in osmotic equilibrium with their environment, together with the experimental discrepancies, and decide that the current theory is not worth preserving. The alternative, that active transport of water is occurring across the walls of most cells and that their apparent equilibrium is in fact a dynamic steady-state, seems to provide a better starting-point from which to appreciate the differences between tissues, and it makes it possible to begin the interpretation of whole ranges of data. Fortunately such changes in outlook occur rarely; but in its short history "Annual Review of Physiology" can boast of a few such papers to which we turn again and again. D. WHITTERIDGE

British Association for the Advancement of Science Mathematical Tables

Vol. 10: Bessel Functions, Part 2, Functions of Positive Integer Order. Prepared on behalf of the Committee for the Calculation of Mathematical Tables by W. G. Bickley, L. J. Comrie, D. H. Sadler, J. O. P. Miller and A. J. Thompson. (Published for the Royal Society.) Pp. xi+255. (Cambridge: At the University Press, 1952.) 60s. net.

THIS volume, to quote the preface, is the last of the series of British Association Mathematical Tables and is thus both the fulfilment of a long-standing promise and the completion of a task. It forms a companion to Part 1 (Bessel functions of orders zero and unity), containing, as it does, tables of functions of integer orders from two to twenty, inclusive.

There is a comprehensive introduction of some forty pages consisting of page-index diagrams, an account of the preparation of the tables and the methods of interpolation used therein, together with a bibliography, a summary of notations and a most valuable list of the definitions of the functions and the relevant formulae.

The tables themselves are divided into eight distinct sections. The first gives $J_n(x)$ for the arguments 0-25 to eight decimal places, and the second a similar table for $Y_n(x)$. In the third and fourth, the functions $e^{-x}I_n(x)$ and $e^xK_n(x)$ appear to eight figures for arguments 0-20. Second differences are provided in all four cases, and the interval of tabulation is generally 0.1, but in smaller arguments sometimes 0.01. The last four sections deal respectively with $J_n(x)$, $Y_n(x)$, $I_n(x)$, $K_n(x)$, the entries here being to ten figures with a uniform interval of 0.1. The ranges of argument are as before, but this time no special provision is made for interpolation.

Meticulous care has been taken in the preparation and reproduction of this series of B.A. Tables by all concerned, and this particular volume conforms to the usual high standards.

J. H. PEARSON

Proteins and Enzymes

By Kaj Ulrik Linderström-Lang. (Lane Medical Lectures.) (Stanford University Publications: University Series, Medical Sciences, Vol. 6.) Pp. ix+115. (Stanford, Calif.: Stanford University Press; London: Cambridge University Press, 1952.) 24s. net.

NO laboratory has devoted itself so long to the fundamental problems of protein chemistry as the Carlsberg, and in these lectures Dr. K. U. Linderström-Lang has presented some of the topics pursued there during the past twenty years. If any short description is possible, it might be said that they truly reflect in the elegant simplicity of experiment and deduction the great tradition of Sørensen. The first two lectures describe the development and application of ultramicro methods in biology, a many-sided research to which Holter's name is inseparably linked. One feels here that artistry and science have shared equally in producing these beautiful methods, which have been applied to such varied material as moths, carnivorous plants, sea-urohin eggs, gastric mucosa, barley and *Chaos chaos*.

Two lectures are devoted to the initial action of proteolytic enzymes on proteins and the conversion of ovalbumin to plakalbumin. The latter has the greatest significance for interconversions which are much more important physiologically—the clotting mechanism and the activation of zymogens. This last topic is itself explored and discussed in relation

to the action of proteolytic enzymes themselves: whether they initially accelerate the opening out of the protein molecule. The methods used, changes of rotation and molecular volume, are characteristically simple.

The last topic deals with the biosynthesis of the peptide bond—not, as the title declares, the biological synthesis of proteins. This is a most useful and precise account. It is appropriate to add that, in contrast to the factual impersonality of much scientific writing, most readers will appreciate the familiar style, the clarity and individuality of the presentation.

KENNETH BAILEY

High Energy Nuclear Physics

Proceedings of the Third Annual Rochester Conference, December 18-20, 1952. Compiled and edited by H. P. Noyes, M. Camac, and W. D. Walker. Pp. iv+110. (New York and London: Interscience Publishers, Inc., 1953.) 2.00 dollars.

THIS record contains a résumé of the talks and discussions offered by the participants to the third annual Rochester conference on "High Energy Nuclear Physics", held during December 18-20, 1952. It is a very attractive record and one of the liveliest I have come across. This is due partly to the excellence of presentation and the topicality of the subject-matter offered. It reflects the spirit of informal discussion by reproducing the contributions in approximately verbatim form, often lightening controversial matters with speech and counter-speech.

The excellent summary by E. Wigner of the "Present Status of the Charge Independence and the Saturation of Nuclear Forces" opens the volume and is followed by contributions from various experts in the field. Next come the following: pion production and pion-nucleon scattering (under the chairmanship of E. Fermi); V^0 particles, generally only found in cosmic rays; and a session on the super-heavy mesons χ , κ and τ . Two chapters on theoretical field calculations and on experimental topics, respectively, complete the conference record. Of special interest to the experimental physicists in the last chapter are such exciting things as μ^- and π^- mesonic X-rays, and the decay of π^0 into positron and electron plus gamma-ray.

On the whole, one realizes the fact that our present knowledge of the properties of mesons and their interactions is very inaccurate and that it offers a wide field for the experimentalist who has access to big accelerators or is expert in cosmic-ray research. This conference report is essential for all research workers in this field and well worth reading by the general nuclear physicist. It costs only two dollars and is printed, fortunately, in big clear type.

E. BREITCHER

A Handbook of Colorimetric Chemical Analytical Methods for Industrial, Research and Clinical Laboratories developed for use with the Lovibond Comparator

Pp. 119. (Salisbury: The Tintometer, Ltd., 1953.) 15s.

THIS handbook consists of a collection of methods of colorimetric analysis using the Lovibond comparator with standard coloured-glass disks appropriate to each determination. In all, sixty different determinations are described, dealing with pH measurements, the analysis of organic and inorganic substances, and clinical determinations of such varied substances as *p*-aminosalicylic acid, blood phosphatase and lead. The introduction and general

description—adequately illustrated—describe the general method of carrying out colorimetric determinations.

The succeeding sections deal with individual determinations, preceded in each case with the relevant references to the scientific literature. The methods, which are clear and concise, have been drawn up in collaboration with laboratories engaged in each determination. As in all colorimetric methods, it is assumed that the preliminary preparation has eliminated interfering substances and that the colour quality given by the test is precisely the same as the disks, which are permanent. As pointed out in the introduction, "if the colour of the test solution is different from the glass standards, it is a sure indication that the reagents are stale or wrong, or the technique has not been followed correctly". The colour quality of the light used is important, as there may be considerable metamerism between the colour of the test liquid and the coloured disks. The operator is therefore directed to use a "uniform source of white light, preferably a north window".

While the modern tendency is for the use of a spectrophotometer or photoelectric colorimeter instead of visual methods, it must be admitted that well-standardized and authenticated colorimetric methods such as described have distinct advantages in simplicity and speed, and avoid certain difficulties associated with complicated instruments. J. KING

Yorkshire Birds

By Ralph Chislett. Pp. viii+335+10 plates. (London and Hull: A. Brown and Sons, Ltd., n.d.) 25s. net.

A NEW work on the birds of Yorkshire is very welcome, as many changes have taken place since Nelson and Eagle-Clarke's book was published in 1906. As is the case elsewhere, Yorkshire has suffered during the past quarter of a century from the increase of industrial development and intensive farming. The clearing of all deciduous woods and replanting with conifers has had a marked effect on the bird-life, and although the decline of game preservation and the breaking up of estates may have been good for birds of prey, it has led to a great increase in carrion crows, magpies and jays.

A chapter is devoted to these changes, and another gives a useful summary of bird migration in Yorkshire, both inland and on the coast. Spurn Point, at the mouth of the Humber, is an important point of arrival for migrants crossing the North Sea, and was formerly a great haunt of collectors. Now there is a trapping station where birds are caught and ringed, and much information is being collected on the movements of migrants on that part of the coast. The Brampton and Flamborough cliffs have long been famous as breeding places for vast numbers of sea-birds, including guillemots, razorbills and kittiwakes. Mr. Ralph Chislett writes that all is not well there: the kittiwakes have increased, but the numbers of guillemots and razorbills are much fewer than formerly, and this, he suggests, is owing to the over-collecting of their eggs and the mortality through oil pollution—a menace to which these birds are very susceptible. Certain species among the land-birds have also decreased; but, at the same time, others have increased. All this is well described in the author's interesting account of each species.

Mr. Chislett is to be congratulated on his volume, which will long remain the standard work on the birds of Yorkshire.

Volume and Integral

By Prof. Werner W. Rogoinski. (University Mathematical Texts.) Pp. ix+160. (Edinburgh and London: Oliver and Boyd, Ltd.; New York: Interscience Publishers, Inc., 1952.) 10s. 6d. net.

THIS small book provides an excellent introduction to the theory of the Lebesgue integral in n dimensions.

Part 1 is devoted to the problem of volume, the geometrical aspect of the integral being stressed throughout the book. First, sets of points are considered, and then the Peano-Jordan definition of content is discussed; this is followed by the Lebesgue definition of measure.

Part 2 first gives the theory of the Riemann integral of a function of n variables, defined geometrically (that is, in terms of 'volume'), using content as the underlying notion of volume. The Lebesgue integral is then dealt with in a similar way, on replacing content by measure. Finally, the theory of the indefinite integral of a function of one variable is discussed.

I agree with the author (see preface) that the elements of the theory of the Lebesgue integral should be included in a mathematical honours syllabus. This book, which is exceptionally clearly written, would well serve the purpose of teaching such matter. Some good examples are provided, with solutions at the end of each chapter; this is an additional recommendation in a book of a purely theoretical character. R. G. COOK

Pétroles naturels et artificiels

Par J.-J. Chartrou. (Collection Armand Colin: Section de chimie, No. 124.) Troisième édition, entièrement refondue. Pp. 224. (Paris: Armand Colin, 1952.) 260 francs.

THIS typically neat, paper-covered little volume, which fits the pocket comfortably, is the third edition, No. 124, of "Collection Armand Colin (Section de Chimie)". The author endeavours to cover a wide field of petroleum technology in 224 pages, size $6\frac{1}{2} \times 4\frac{1}{2}$ in. He states his object at the outset: to study physical and chemical properties of petroleum; exploitation and refining; a chemical industry based on petroleum products; substitute hydrocarbons and lubricants. Actually, he goes much farther than that curriculum, ambitious though it is for small space. Twelve chapters describe composition, chemical, physical properties of petroleum; geology, surface indications and exploration; exploitation by drilling, wells, shafts, galleries; storage, transport; refining; analysis, control of products; economic applications of products including chemically derived materials; world production; hazards in the oil industry. There is an afterthought on *osokerite* and asphalt (two pages!); and an omnibus chapter, which includes oil shales, low-temperature carbonization, hydrogenation and synthetic products, completes the study. To me it seems a herculean task to attempt to cover in narrow compass all aspects of such a highly integrated and specialized technology as petroleum as it exists to-day, even in title. At best, it means synopsis; at worst, much severed outline. To the layman, much of this text is beyond him. To student or oil technologist, modern literature is now prodigious in its specialized subjects, and outlines as such are outmoded. Maybe there is a 'midway' public in French-speaking countries to which this little work will appeal; to this extent I wish it well. H. B. MILNER

THE AMATEUR SCIENTIST IN BRITAIN (2)*

By R. BRIGHTMAN

IN the physical sciences the amateur is still rendering services. Maurice Gorham, former head of the Television Service of the British Broadcasting Corporation, has pointed out that broadcasting owes its resuscitation in the 'twenties to the amateurs¹. Their activities, enthusiasm and incessant demands, culminating at the end of 1921 in a petition to the Post Office from sixty-three societies representing 3,300 amateurs asking for wireless telephony transmissions, "primarily to serve the scientific purpose of improving the receiving arrangements", but referring to weather reports, news, etc., which were already being received from foreign wireless stations, in a way that showed clearly that what they wanted went beyond purely scientific tests. This time the Post Office yielded and authorized the Marconi Company to broadcast speech and music for the amateurs, to the extent of one programme of fifteen minutes duration each week, and thus the first authorized broadcast made from Writtle on February 14, 1922, is due mainly to the activities of amateurs. At the present day, a new organization, to be known as the Radio Amateur Emergency Network, is being formed. When it is complete it will include some fifty key stations and about four hundred auxiliaries, all operated by amateurs. Most of the key stations are already linked. The amateurs operating the fifty key stations have all undertaken to provide emergency sources of power independent of the public electricity supply.

Again, Sir Edward Appleton has borne witness to the value of the pioneer work of D. J. Heightman and other amateurs in connexion with solar-radio noise². Attention, he points out, was first attracted to this phenomenon by the reports of wireless amateurs who, round about the period of the last sunspot maximum, noticed the existence of a curious hiss in their receivers on wave-lengths of about ten metres, which they found to occur in day-time only, and to be associated with periods of solar activity. During the War, with the more sensitive and more directional ultra-short-wave receivers in operation, many further reports of the reception of this noise became available, and Sir Edward Appleton used the period of pronounced sunspot activity, January 30 to February 14, 1946, to make a special detailed study of the phenomena. His examination of the evidence available confirms the theory he and J. S. Hey had already advanced that the noise is due directly to ultra-short-wave electromagnetic radiations, which originate in active areas on the sun, and travel from the sun to the earth with the speed of light.

The intense radio-wave emissions from sunspots were also first recorded by war-time operators on Army G.L. equipment. When the V2 rocket bombardment of London began, every method of giving even a few seconds warning was explored. Among these, radar equipments used by Anti-Aircraft Command were modified in the hope that the rockets would give a transient radar echo as they travelled high up in the atmosphere³. They did, but it was soon found that short-lived echoes were obtained

and warnings given when no rockets were about. These spurious echoes were studied by J. S. Hey and his colleagues in the Army Operational Research Group, who eventually concluded that they were caused by meteors in the earth's atmosphere.

It is, of course, scarcely correct to ascribe such work to purely amateur effort. It is unlikely, for example, that anything would have arisen from this latter work had not a fully qualified scientist been responsible for investigating all such unusual occurrences, or had not the members of the Field Study Course been excavating under expert guidance. They do, however, illustrate the force of an observation made by Mr. Justice Lloyd-Jacob in his Bernard Dyer Lecture to the Society of Public Analysts⁴. Mr. Justice Lloyd-Jacob, suggesting that the most promising areas for future scientific growth are those that lie between the various well-established scientific fields, stressed the importance of collaboration of the right kind if these fields are to be developed. What is wanted, he suggested, is not so much the skill to experiment in the field of another scientist, but the competence to understand, to criticize and to appreciate the experiment and the results that the experiment secures. Upon such lines the most useful teamwork was done during the War, and had not secrecy considerations prevented the publication of many of the details of this collaboration, the concepts and characteristics of the scientist would not have remained so unfamiliar to most of his fellow-men. Mr. Justice Lloyd-Jacob observed that some better understanding of the scientist might have saved him from those dangers to which mob hysteria over nuclear-fission appear to expose him. It needs only superficial acquaintance with the outcome of security investigations in the United States, for example, to appreciate how real is the danger to science itself to which Mr. Justice Lloyd-Jacob alludes.

There are other reasons, however, why the wider public appreciation of the scientist and his work is desirable. In the introduction to his "History of the Rise and Influence of the Spirit of Rationalism in Europe", published in 1865, W. E. H. Lecky wrote:

"But when towards the close of the eighteenth century the decline of theological passions enabled men to discuss these matters in a calmer spirit, and when increased knowledge produced more comprehensive views, the historical standing-point was materially altered. It was observed that every great change of belief had been preceded by a great change in the intellectual condition of Europe, that the success of any opinion depended much less upon the force of its arguments, or upon the ability of its advocates, than upon the predisposition of society to receive it, and that that predisposition resulted from the intellectual type of the age. . . .

"The pressure of the general intellectual influences of the time determines the predispositions which ultimately regulate the details of belief; and though all men do not yield to that pressure with the same facility, all large bodies are at least controlled. A

* Continued from p. 565.

change of speculative opinions does not imply an increase of the data upon which those opinions rest, but a change of the habits of thought and mind which they reflect. . . .

"... The doctrine, that the opinions of a given period are mainly determined by the intellectual condition of society, and that every great change of opinion is the consequence of general causes, simply implies that there exists a strong bias which acts upon all classes of men and eventually triumphs over every obstacle."

Mr. Justice Lloyd-Jacob's remarks remind us of Lecky's doctrine of the climate of opinion; but whereas Lecky had in mind particularly the way the discoveries of physical science were entrenching upon the domain of the anomalous and the incomprehensible, and by enlarging our conceptions of the range of law, and revealing the connexion of phenomena that had formerly appeared altogether isolated, had formed a habit of mind far beyond the limits of physical science, we, in our day, are more concerned with the way in which public ignorance or hysteria can limit the operations of science itself.

To take one or two examples:

The Report on the Conservation of Nature in England and Wales, published in 1947, observes¹:

"In the long run the success of wild life conservation must depend predominantly on the completeness with which wild life problems and their implications are known, and on the extent to which public opinion accepts them and therefore gives support to the necessary measures of conservation."

"We are impressed with the futility of pursuing wild life conservation policies which are not widely understood and backed by public opinion, and of creating a multiplicity of offences or restrictions upon the liberty of the individual, in order to curb the misguided activities of very small sections of the population."

Similarly, Sir Arthur Tansley recorded the view that the establishment and fruitful functioning of national Nature reserves and a biological service would not be secured without a greatly increased permeation of the general mind with the outstanding importance of their objects.

Dr. E. A. R. Ennion, addressing in August 1950 the Conference of Delegates of Corresponding Societies at the British Association meeting in Birmingham, likewise observed²:

"Reserves cannot be administered properly by remote-control committees whether of strictly scientific or of predominantly sentimental composition. Still less could reserves be supervised successfully from a window in Whitehall. Their ultimate safeguard lies in the studied care and vigilance of amateur field naturalists up and down the land."

In August 1951, Dr. D. A. Allan³, surveying the "Scottish Scene" in his presidential address to the same Conference at Edinburgh, remarked that the trained biologist required to supervise Nature reserves and to carry out ecological research involved, needed the support of "a special Home Guard of local amateur naturalists, including botanists, entomologists, ornithologists and zoological specialists".

Besides this scientific and practical aspect which obviously calls for a real effort at education, there is a cultural or spiritual aspect which is no less important. As the Huxley Committee observed⁴, the educational benefits to be had from a constructive wild-life policy extend beyond the cultivation of a

healthy public opinion and the technical training of science students to the wider sphere of general and adult education. In this context there is a quotation from the third report of the Nature Reserves Investigation Committee: "A serious student, whatever his calling, who could visit and have intelligently demonstrated to him even a good example of the sites here proposed, would have received a liberal education in one of the most stimulating and formative fields of thought". By building up an appreciation of the interest and beauty of Nature and public consciousness of the aims of conservation, the Huxley Committee considers that the adult educational facilities provided in the Nature reserves would complement and ease the work to be done in National Parks. Now that the Nature Conservancy is well established, it can be confidently expected that, with Mr. E. M. Nicholson as its director-general, who is probably even better known as an ornithologist than as the senior Civil servant who had been secretary to the Lord President's office since 1945, there will be no failure to cultivate the amateur's support and co-operation, and that the Conservancy will encourage and, where possible, extend voluntary efforts in the field of research, especially ecological research, for which it is responsible.

This is not all, however. Prof. S. W. Wooldridge has stated that at no time did the youth of Britain need more greatly to be shown the mental stimulus combined with solace of mind and spirit which come from learning to read and understand the country⁵. It is of vital importance that interest in Nature and in living things should be stimulated and encouraged by every possible means. Only by strengthening this side of people's minds can we hope to counter excessive preoccupation with stark mechanism and the crude materialism to which it often leads—so dangerously characteristic of modern civilization—by a deeper understanding of living beings and of life. Sir Arthur Tansley⁶ also has urged that this is as important to the continuation of civilization as an ever-deepening understanding of Nature and of the complex structure and working of her productions is the very foundation of most of man's practical activities—in the first place his own physical and mental health, then agriculture and the care of animals, and then such pursuits as forestry, control of pests, water supply, drainage, and so on.

The work of the Council for the Promotion of Field Studies, formed in December 1948, largely on the initiative of Mr. F. H. C. Butler, its present director, is appropriately considered in this context. Briefly, the aims of this Council, which was incorporated on June 13, 1946, are to provide facilities for every aspect of field-work at first hand, and to set up for this purpose residential field-study and research centres, distributed throughout the country, in localities selected for the richness and variety of their ecological features, geological and geographical interest and archaeological and historical importance. The field-centres are available alike to all serious workers in the field, whether amateur or professional, whether as individuals or as members of a class from a school, training college or university; from a county college, technical college or youth service; whether as independent workers or as members of a research team, learned society or other corporate body. The Council wishes to co-operate closely with local societies and field clubs, and through the centres should also be able to play an important part in the training of the community in sound knowledge,

aesthetic appreciation and proper use of the countryside. The centres are intended just as much for the individual "amateur nature lover" as for parties from universities, training colleges and schools; in fact, it is one of the aims of the Council to encourage and help the ordinary person with an interest in some branch of natural history who wishes to learn more of this or allied subjects. It is precisely because they are not directly concerned with education that 'amateurs' contribute to a mixed party the spirit of genuine interest and enthusiasms which has nothing to do with examination results. Their contribution to any course is correspondingly valued. They are so often people of wide experience that they have a special contribution to make to discussion and argument on any course, and the work of the centres suffers accordingly when there is none in residence.

Since the first of the field-centres opened its doors at Flatford Mill in May 1946, more than 15,000 resident students have passed through them and the amateur naturalist has been accepted on a really large and comprehensive basis. There are at present four such centres situated in totally contrasting types of country. Flatford Mill itself is specially well placed for the study of hydrobiology, and it is hoped here to develop besides long-term recording of hydrobiological conditions, including temperature changes in a slow-moving river, a training ground for ecological research. The Juniper Hill Field Centre, near Dorking, offers opportunities for the geographical interpretation of landscape, the siting and growth of settlements, plant and animal ecology and general nature study on the North Downs, the western Weald and the outer fringe of the London basin. The Dale Fort Centre, near Haverfordwest in Pembrokeshire, is particularly adapted for the study of bird life and marine biology and the ecology of a rocky coast. It offered in August 1952 for family parties, as an experiment, a holiday course based on the wind and the sea. An integral part of this Centre is the Skokholm Island Bird Observatory. The Malham Tarn Field Centre near Settle offers opportunities for the study of bird life and mammal life in characteristic limestone regions of the Yorkshire dales, including also courses on insects and on fungi, liverworts and mosses. One feature of the work at this Centre has been the annual collaboration since 1950 of the Royal Meteorological Society in a course held in September, and each of these four centres estimates the students in residence, generally for a week at a time, at 1,000-1,200 for the season.

While the need for facilities for field-work in Britain is thus increasing and the opportunities which the Council can offer are more important year by year, the Council finds increasing difficulty in maintaining its centres. It has already been compelled to raise its weekly charges to students to five and a half guineas, and although some firms like Imperial Chemical Industries, Ltd., have made substantial annual grants under deed of covenant in favour of the Council, much more support is required both from industry and from the scientific societies and other bodies if all the possibilities which the Council's work offers for encouraging the activity of both the professional and the amateur scientist in field studies are to be utilized to the full.

It should be apparent from the foregoing account that already much is being done in Great Britain to close the gap between the professional scientist and the amateur, or indeed the layman generally. In few

countries have amateur naturalists made such important contributions to biological knowledge over so long a period as in Great Britain, but since the War there have been remarkable developments in other countries. In a paper reviewing the tenth International Ornithological Congress at Uppsala in 1950, where the large British party included characteristically strong amateur elements, Dr. Julian Huxley referred to the way the interest of the amateur in ornithology had been enlisted since the previous Congress in 1938. Besides the founding of the British Trust for Ornithology, which carries out various scientific investigations almost wholly from the efforts of amateurs, the Swedish Ornithological Society had grown to more than 1,500 members, mostly amateurs, since its foundation in 1946, and there have been similar developments in the United States, Holland and elsewhere. As a result of this, many men and women who would, at best, have become amateur bird-watchers or sentimental bird lovers, have become interested in the scientific aspects of bird life, and have had the satisfaction of helping in research and the advancement of scientific knowledge. Dr. Huxley instances important new knowledge, for example, on the fluctuation in numbers of particular species (like the common heron or the great crested grebe) within a country or region over a period of years, or the relation of clutch-size and of egg and fledgling mortality to geographical position and climatic variation, as discovered only through the co-operative efforts by amateurs. The British Trust for Ornithology itself, which exists to encourage observation by amateurs and to publish the results, has, in addition to the inquiries it has completed into the numbers and habits of rooks, the decrease of the corn-crake and the distribution of the woodcock, for some years been investigating the changes in the population of heronries in relation to the weather and the remarkable spread of the fulmar. The new Observatory on Bardsey Island, off the Llyn Peninsula of Caernarvonshire, which is now making an appeal for funds on the lines adopted by the Fair Isle Bird Observatory of Northern Scotland, is the latest of twelve such observatories to be established in the British Isles, and the fourth along the west coast. It owes its foundation to the initiative of the West Wales Field Society and the Birmingham and West Midland Bird Club, and will offer opportunities for work by amateurs, particularly in setting up the bird-catching traps and devices for the capture, marking with numbered leg-rings, and release of migratory birds.

In the United States in 1938 the Carnegie Corporation and the American Philosophical Society set up a Committee on Education and Participation in Science which surveyed the activity of more than seven hundred amateur scientists in the Philadelphia region and helped organize a number of research projects in which very many more participated. Out of this came "The Amateur Scientist", a book written by the secretary of the committee, W. Stephen Thomas. At about this time, too, a Committee on Private Research, also supported by the Carnegie Corporation, was set up at Western Reserve University for work in the Cleveland area. Many of the studies of amateurs with which it was concerned were in the sciences. The activities of this committee are described in a book by its director, William S. Dix, entitled "The Amateur Spirit in Scholarship". The War unfortunately prevented an extension of

these promising experiments. The American point of view is also well indicated in the presidential address to the American Association for the Advancement of Science of E. W. Sinnott, in December 1949¹⁷. In that address, entitled "Ten Million Scientists", Dr. Sinnott pointed out that we sometimes forget the vast areas where facts and principles of great scientific value may be discovered with no more complex tools or techniques than are at the command of any intelligent layman. He instanced the exact distribution of plant and animal species, the records of flowering dates, the analysis of tree-ring chronology, the variability of wild species, bird censuses and the records of bird and insect migrations, the study of peat borings, the collection and identification of fossils, the distribution of minerals, detailed local weather observations, records of meteorites and of variable stars, time-lapse photography, and problems of radio transmission, as but a few of the many fields open to study by the amateur scientist, and he added that a fresh point of view and freedom from bias have often led the amateur to discoveries that his more inhibited professional brother had overlooked.

The latest Directory of Natural History Societies lists some 124 such societies in Great Britain. Some societies, such as the Geologists' Association, Geographical Association, Amateur Entomologists' Society, Radio Society of Great Britain and British Astronomical Association, have among their members a considerable proportion of young people. The Amateur Entomologists' Society has some two hundred members in a special category of junior membership, and the Radio Society of Great Britain has about five hundred. The Royal Society for the Protection of Birds, besides having a special subscription for those under twenty-one, organizes a Junior Bird Recorders' Club. This was founded in 1943 and has now three thousand members between eleven and eighteen years of age. Members record observations of birds, which are used in producing an Annual Bird Report. Altogether there are some four hundred societies in Great Britain the interest of which include one or more branches of science, and these have already co-operated in such matters as the Land Utilization Survey; British Museum (Natural History), bird-ringing scheme, insect immigration scheme; London Natural History Society, bird report; Royal Meteorological Society, phenological report; Rothamsted Experimental Station and National Institute for Agricultural Botany, crop experiments.

With the growing dependence of scientific work upon State, or at least public rather than private support, it is more than ever important to secure such a public understanding and favourable climate of opinion if scientific work is not to be liable to continual and frustrating interruptions at every time of financial stringency. A volume of studies and sketches which Prof. J. Simmons published in 1952 under the title "Parish and Empire"¹⁸ constituted an eloquent plea for field research and historical approach over a wide range of what may be termed local studies. He directs attention, for example, to the general neglect of industrial history and shows how parish studies can be linked up with national and imperial history. He indicates how the study of local history can contribute not merely to the clearer understanding of some of our modern problems, but also to redress some of the dangers inherent in specialization to-day. Local studies of this type

could make their own contribution to the promotion of a wider general understanding in the community of the nature of scientific work and thus indirectly to the creation and maintenance of the conditions in which scientific activities truly flourish. That, as has been indicated, is one essential element in securing the continuous public support which the effective prosecution of scientific effort under the conditions of to-day demands. It is fostered also by the very existence of the amateur scientist and his wide distribution among all sections of the community. Lastly, as for the past three centuries, the contribution of the amateur is important in itself: even to-day, without the help of the amateur scientist the prosecution of research on the scale desirable into many problems of ornithology, meteorology and other problems embraced in ecology would be impossible. In such fields, with Britain's limited resources of scientific man-power, the co-operation and enthusiastic support of the amateur scientist are indispensable for the most effective deployment of our trained professional scientists.

THE OLDEST DATED MINERALS OF THE RHODESIAN SHIELD

By PROF. ARTHUR HOLMES, F.R.S.
University of Edinburgh

FOR some years it has been suspected that the Rhodesia-Tanganyika Shield might include some of the oldest rocks of the African continent¹. This has now been confirmed by the dating of monazites supplied by Dr. A. M. Macgregor and the Director of the Geological Survey of Southern Rhodesia. Through the good offices of Dr. F. H. Burstall, these minerals have been analysed chemically at the Chemical Research Laboratory, Teddington, for lead, uranium and thorium, and samples of pure lead iodide prepared from each. The proportions of the isotopes in the lead of these samples have been determined by Messrs. William C. Erickson and John Hoffmann in the laboratory of Prof. Alfred O. Nier at the University of Minnesota. The generous collaboration of these friends and fellow-workers is gratefully acknowledged.

The analytical data are recorded in Table 1, together with the crude, uncorrected ages, as read from Wickman's graph². The highest uncorrected

Table 1

(Analyses by the Chemical Research Laboratory, Teddington).

	Pb	U	Th	Pb(U+Th)	U/(U+Th)	Uncorrected age
1.	0.84	0.074	2.30	0.188	0.03	2,630 m.y.
2.	0.96	0.19	9.36	0.100	0.02	2,020 m.y.
3.	0.68	0.09	8.15	0.070	0.01	1,500 m.y.

1. Monazite from pegmatite, Ebonite Tantalum Claims, Bikita District, Southern Rhodesia.

2. Monazite from pegmatite, Jack Tin Claims, north of Salisbury, Southern Rhodesia.

3. Monazite concentrate from alluvium derived from "Lower Basement" rocks, Irumi Hills, about 90 miles east of Broken Hill, Northern Rhodesia.

age, that of the Bikita monazite, 2,680 million years (m.y.), needs very little correction, which is a highly satisfactory result in view of the extreme age of the mineral.

The first published indication of the great age of the Southern Rhodesian pegmatites was provided by Ahrens², who found the mean 'ages' of nine lepidolites, as determined by the strontium/rubidium spectrochemical method, to range from $1,900 \pm 200$ to $2,950 \pm 300$ m.y. Four of the specimens, including the 'oldest', were from the Bikita District, the mean of nineteen determinations (ranging from 1,700 to 3,800 m.y.) being $2,400 \pm 200$ m.y. It is stated that all these measurements were calibrated in terms of a standard lepidolite from south-east Manitoba, the age of which was taken as 2,300 m.y. This value is almost certainly too low, 2,500 m.y. being more probable⁴. Adopting this figure, the mean of all Ahrens's Bikita results is increased to 2,700 m.y. The close agreement with the corresponding lead age is of great interest; but the wide range involved (1,980–3,750 m.y.) emphasizes Ahrens's own warning² that as yet the strontium ages "of these most ancient rocks should not be taken too rigorously". In addition to the random errors inherent in spectrographic analysis, there appears to be, *inter alia*, a systematic error leading to abnormally high 'ages', the source of which is now being actively sought. The discrepancies cannot be altogether due to the original presence of inherited strontium, for even mass-spectrometric methods give results that are manifestly too high; for example, for lepidolite from Pope's Claim, Southern Rhodesia, belonging to the same cycle of

plutonic activity as the Bikita minerals, an 'age' of 3,740 m.y. has been claimed⁴, whereas Ahrens's estimate for lepidolite from the same locality was only $2,150 \text{ m.y.} \pm 10$ per cent. (Since this article was completed, Prof. J. T. Wilson has informed me that the age of microcline from Pope's Claim has been determined in his laboratories at the University of Toronto from the ratio of radiogenic lead-207 to radiogenic lead-206 and found to be $2,600 \pm 100$ m.y. I am indebted to Prof. Wilson for permission to announce this important result.)

The older rocks of Southern Rhodesia are curvilinear synclinal schist belts enwrapped by migmatites and granites. Three systems have been distinguished in the schist belts: (1) the *Sebakwian*, characterized by granulites and metamorphosed ultrabasic rocks; followed, after folding, granitization and erosion, by (2) the *Bulawayan*, characterized by banded ironstones and volcanic rocks, including pillow lavas; followed in turn by (3) the *Shamvaian*, a mainly sedimentary system which, together with the older rocks, was later folded and locally granitized. A suite of pegmatites of lepidolite-greisen type with a lithium, beryllium, tin, tantalum, tungsten mineralization is associated with the later granites. Of many of the mineralized pegmatites it is only known by direct evidence that they are post-Bulawayan, but since some of them cut the Shamvaian formations and the others have not been metamorphosed, it is probable that the whole suite is post-Shamvaian⁵.

The Bikita monazite (Table 2) is a concentrate from a post-Bulawayan tantalite-bearing pegmatite situated about four miles south-west of the main Bikita tin field⁶. If the proportion of lead-204 can be regarded as negligible, the four 'ages' are in remarkably close agreement. If an extreme correction for original or inherited lead be made, taking lead-204 as 0.0007, the four 'ages' become (respectively as in Table 2):

$2,600 \pm 30$; $2,870$; $2,615 \pm 15$; $2,640 \pm 25$ m.y.

The sequence of the first three⁶ indicates a very slight deficiency of uranium, which might be due to natural alteration of the mineral or to a slight error in the analysis. In neither case would this affect the

OBITUARIES

Dr. F. M. Penning

age calculated from the ratio of lead-207 to lead-206, which may therefore be accepted as a minimum value. Apart from the standard deviation, one can only conclude that the age of the Bikita monazite is less than 2,680 and more than 2,600 m.y., suggesting that the most probable age is about 2,640 m.y., as given by the ratio lead-208 to thorium.

The monazite from the Jack Tin Claims (Table 2) is a concentrate from a post-Bulawayan pegmatite worked for tin and tantalum north of Salisbury. The 'age pattern' in this case clearly points to loss of lead⁹, in which case the most reliable age is that given by the ratio lead-207 to lead-206, namely, $2,660 \pm 10$ m.y.

The monazite from the Irumi Hills of Northern Rhodesia (Table 3), near the southern extremity of the Katanga pedicle, is a concentrate from alluvium derived from the rocks of the "Lower Basement" Group. Although nearly all the crystals are clear and apparently unweathered, the 'age pattern' indicates that the mineral has, in fact, been considerably altered. Loss of lead is the dominant effect, accompanied in this case by subsidiary loss of uranium. The only age indicator of value is the ratio lead-207 to lead-206, which remains unaffected by recent weathering and would be only slightly reduced by alterations that occurred long ago⁹. The age given by this ratio, $2,620 \pm 10$ m.y., may therefore be a trifle less than the true value. The accordance of this result with those recorded above adds convincing support to Guernsey's provisional suggestion—based on lithological and tectonic similarity—that the Lower Basement rocks of Northern Rhodesia may be partially equivalent to the Bulawayan System¹⁰.

The Bulawayan rocks represent sediments and lavas that were deposited or erupted at the earth's surface considerably earlier than the period of pegmatite formation here dated at about $2,640 \pm 40$ m.y., especially so if the pegmatites concerned are post-Shamvaian, as is highly probable. Since these pegmatites are not only the oldest dated examples known in Africa but are also the oldest yet recorded for any continent, it is interesting to direct attention to their bearing on the time during which life is known to have existed on the earth. In 1935, Dr. A. M. Macgregor detected algal structures in graphitic limestone (33 miles north-north-east of Bulawayo) associated with cherts and lavas low down in the Bulawayan System, which at that time was known as the Greenstone System. In 1941, the structures were described and figured¹¹. This important discovery by Macgregor, and the age determinations now recorded, provide indubitable evidence that life has existed for at least 2,600 m.y. and probably for considerably longer than 2,700 m.y.

FRANS MICHEL PENNING was born on September 12, 1894, at Gorkum in The Netherlands. He studied physics at the University of Leyden under Kamerlingh Onnes, and his thesis on isopycnic curves of gases at low temperatures is in keeping with the Leyden traditions of those days. In 1924 he joined the research laboratories of the Philips Company at Eindhoven, and there he remained until his death on December 6, 1953, devoting his activities almost exclusively to the study of the electric discharge in gases, a field in which he soon became a prominent figure.

A characteristic feature of his work was his continual effort to obtain reproducible results under well-defined conditions. With great skill and patience he carried out a number of carefully designed experiments to determine fundamental constants relating to discharges in gases. This work also led to brilliant new discoveries.

Penning was the first to recognize that the breakdown potential of inert gases can be profoundly modified by small quantities of other gases which may become ionized by collision with metastable atoms of the original gas. This concept enabled him not only to explain the discrepancies between existing data but also to discover a number of new and striking phenomena.

A second aspect of his work dealt with discharges in magnetic fields. One of his results was that, in a magnetic field with a certain electrode configuration, a discharge can subsist at very low pressures. This led to the development of the Penning type of ion source and of the Penning ionization gauge, both of which are valuable tools in modern experimental technique.

In the years after the Second World War, Penning made further important progress in obtaining reproducible values of the cathode fall on a molybdenum electrode by showing how the influence of oxides and other impurities can be eliminated by an elaborate sputtering technique. This work led also to the development of a new stabilizing tube.

Mention should also be made of his article with de Groot on the excitation of quantum transitions by collisions, in "Geiger und Scheel's Handbuch der Physik" (1930), and of the well-known review article with Pruyvesteyn (*Rev. Mod. Physics*, 1940).

Although handicapped by delicate health, Penning was not only a very hard worker but also a man with broad interests. Those who had the privilege of knowing him personally will remember him as a loyal friend and unselfish colleague, who to a rare degree had attained harmony between his personal faith and his daily life.

H. B.-G. CASIMIR

Dr. N. G. Horner

DR. NORMAN GERALD HORNER, who died on March 7, was editor of the *British Medical Journal* from 1928 until 1946, and for eleven years before that he was assistant editor under Sir Dawson Williams. Dawson Williams was an exacting chief, who was held in awe by his staff and colleagues; but Horner, a man of very different constitution and manner, became his devoted disciple, even to the extent of a (probably unconscious) change of literary

style. In his early days, Horner—one of those people who have a feeling for words and a sense of their value—contributed lightheartedly to his school magazine at Tonbridge, and to St. Bartholomew's Hospital *Journal*, of which he was editor for a time; but when, after serving in the First World War, he joined the staff of the *British Medical Journal* he quickly acquired its discipline and devoted himself to the precise writing and editorial revision which a scientific journal demands. His use of language was scrupulous, and any infelicity or slovenliness in phrasing he would regard as a form of discourtesy. But he was also a man of businesslike ability and resource, exemplified particularly on two occasions, one of them the general strike of 1926, when two issues of the *Journal* appeared in a very attenuated form indeed, but nevertheless appeared, and the other the occasion in 1941, when the printing office was destroyed in an air raid and the most extraordinary improvisations had to be made.

In the latter years of his editorship the British Medical Association became responsible for a number of special journals dealing with different aspects of medicine. Some eight of these were running by the time Horner left Tavistock Square, and although he did not take a major part in starting them they owed a good deal to his suggestions and to the tradition of responsible editorship which he always followed and which he strove to inculcate in others.

Apart from his editorial work, his interest was in the history of medicine. His M.D. thesis in 1922 was on the growth of general medical practice in England. He was honorary secretary and afterwards vice-president of the Section of History of Medicine of the Royal Society of Medicine. After his retirement he assisted in the compilation of the "Medical History of the Second World War".

Horner was editor during a troubled period which comprised not only a world war but also vital change in the medical profession itself. He was handicapped by ill-health; but he maintained throughout his years of office a great integrity, a desire quietly and without special recognition to serve the profession to which he belonged, and to his colleagues and staff he was invariably sympathetic and ready to give a discerning praise where praise was due.

Prof. P. C. Sarbadhikari

DR. C. P. SARBADHIKARI, the well-known Indian cytologist, who died on December 27 in his fifty-sixth year, was professor of botany and head of the Botanical Department of the University of Calcutta. As a young man he studied under the late Sir John Farmer at the Imperial College of Science and Technology, London, and obtained the D.Sc. of the University of London for a series of researches on the cytology of *Osmunda* and *Doodia*. He also studied for shorter periods at Wisley, Kew, Merton, Berlin-Dahlem, and at the University of Paris under Prof. Guillaumond. In 1925 he was appointed lecturer in botany at University College, Colombo, and later became professor there. In 1947 he went to Calcutta to the post which he occupied at the time of his death.

Prof. Sarbadhikari was the author of numerous papers on a variety of botanical topics. His chief contributions lay in the field of morphology and cytology. Specially notable are his researches on the cytology of apogamy and apospory in ferns. A man of considerable culture, he did much to develop botanical study and research in India.

NEWS and VIEWS

Mathematics at Glasgow: Prof. T. M. MacRobert

PROF. T. M. MACROBERT, who retires in September from the chair of mathematics in the University of Glasgow, has made valuable contributions over the past thirty-five years to the theory of various special functions of analysis. His earlier papers dealt mainly with asymptotic expansions of these functions, and were followed by papers dealing with the addition theorem for Legendre functions, and series and integrals of these functions regarded as functions of their degrees. In 1937 Prof. MacRobert introduced the *E*-function, a generalized hypergeometric function, which has proved extremely fruitful for the study of confluent hypergeometric, Bessel and Legendre functions. His more recent papers are mainly concerned with the study of the properties of the *E*-function. He is the author of a number of well-known treatises on mathematics, of which the best known are "Functions of a Complex Variable" and "Spherical Harmonics". During his twenty-seven years as head of the Department at Glasgow, Prof. MacRobert has seen a large increase in the numbers of his staff and of his students, and it was on his initiative that a major scheme of reconstruction was carried out in 1950, involving the conversion of a large hall into a library and a set of lecture, tutorial and staff rooms. Prof. MacRobert was a member of the group of mathematicians who

founded the Glasgow Mathematical Association in 1927. He has taken a prominent part in all its activities and has been the moving spirit behind the inauguration of its *Proceedings*, which, published with the co-operation of the University Court, were first issued in 1951.

Prof. R. A. Rankin

PROF. MACROBERT will be succeeded by Prof. R. A. Rankin, at present Mason professor of pure mathematics in the University of Birmingham. Prof. Rankin was appointed to the Birmingham chair in 1951 (see *Nature*, 167, 840; 1951).

Cytogenetics in the University of London:

Prof. P. C. Koller

THE University of London has conferred upon Dr. Pao Charles Koller the title of professor of cytogenetics, in respect of the position which he holds in the Chester Beatty Research Institute (of the Institute of Cancer Research, Royal Cancer Hospital). Dr. Koller has successively worked at the Kaiser Wilhelm Institute, Berlin (under Prof. R. Goldschmidt), at Cambridge where he studied genetics under Prof. R. C. Punnett, at the Institute of Animal Genetics in the University of Edinburgh (with Prof. F. A. E. Crew), at the Biological Research Institute, Tihany, as head of the Department of Genetics, and at the

John Innes Horticultural Institution with Dr. O. D. Darlington. He also spent one year in the California Institute of Technology, as Rockefeller Fellow, under Prof. T. H. Morgan. Before the Second World War he was closely associated with Prof. H. J. Muller in an investigation of the cytological effects of ionizing radiations on normal and malignant cells, and was later engaged in research on the effects of mustard gas, lewisite and similar substances for the Committee on Chemical Warfare. Dr. Koller was appointed to the Royal Cancer Hospital in 1944, and to the Chester Beatty Research Institute in 1946, where he has carried out a special investigation of the chromosomal and other abnormalities induced by chemical and physical carcinogens. He is the author of numerous papers in the scientific literature, including a specially notable series on the genetical and mechanical properties of the sex chromosomes in a variety of animal species.

George Newport, F.R.S. (1803-54)

GEORGE NEWPORT, who died a century ago on April 7, 1854, is an impressive example of a man who raised himself from a humble origin to scientific eminence and who, despite his lack of early training, made a number of original and enduring contributions to natural history. Born on July 4, 1803, at Canterbury, the son of a wheelwright, he was from early boyhood fond of reading and drawing and was an ardent collector of insects. Deciding on a medical career, he entered the University of London (University College) in 1832, and three years later became a member of the College of Surgeons. He took up surgical practice in London, but was far too interested in microscopical studies to earn his living. Fortunately he had many influential friends, and in 1847 Sir James Clarke secured for him a pension from the Civil List of £100 a year. A patient, accurate observer and a facile dissector, Newport published several important papers (*Phil. Trans. Roy. Soc.*), and his communication in 1851 entitled "On the Impregnation of the Ovum in the Amphibia", in which he demonstrated that impregnation by spermatozoa is the result of penetration and not of mere contact, won him one of the Royal Society's Royal Medals. Many honours came his way in his short life: he was elected an honorary member of the College of Physicians in 1843, a Fellow of the Royal Society in 1846, and a Fellow of the Linnean Society in the following year, and served as president of the Entomological Society during 1844-45. He died at the early age of fifty-one of a "fever of a typhoid character".

The Scottish Economic Society

THE Scottish Economic Society is the new name of the Scottish Society of Economists, which was founded in Edinburgh in 1897, and was for a long time associated with the name of Prof. Shield Nicholson, its first president. Its revised constitution, with its new name, was ratified at a meeting held in the University of Edinburgh on March 16. The Society's chief aims are to advance the study of economic and social problems on the widest basis, in accordance with the Scottish tradition of political economy inspired by Adam Smith, and to encourage the discussion of Scottish economic and social problems. In furtherance of these aims, it published on March 16 the first issue of its new journal, the *Scottish Journal of Political Economy*, to appear three times a year. Some part of each issue will be devoted

to Scottish affairs, either in articles, or in editorial notes, statistical notes on recent social and economic trends, or reviews or review-articles dealing with recent books or official papers relative to Scotland. But there is no intention to limit the contents of the *Journal* either to Scottish contributors or to Scottish problems. The subject-matter of political economy will be interpreted widely, in the tradition of Adam Smith, and articles on economic theory, economic history, sociology, demography and administration, as well as economic theory, will be considered. It is designed to appeal to a wide audience—not exclusively one of professional economists, but including, for example, historians, business men, bankers, accountants, actuaries, Civil servants, trade unionists, and all serious students of Scottish affairs. Members of the Scottish Economic Society, whose annual subscription is one guinea, will receive the *Journal* without additional charge.

The first president of the new Society is Lord Bilsland, banker and industrialist, and chairman of the Scottish Council (Development and Industry). The vice-presidents are Sir Alexander Gray and Dr. M. T. Rankin, who was a senior office-bearer of the old Society. The editor of the *Journal* is Prof. A. K. Cairncross, of the chair of applied economics in the University of Glasgow, who is assisted by an editorial board consisting of the professors of political economy in the four Scottish Universities and the secretary of the Society, Mr. T. A. F. Noble, lecturer in political economy, King's College, University of Aberdeen. The other members of Council are widely representative of business, banking and professional interests in each University region of Scotland. The treasurer of the Society, to whom applications for membership should be sent, is Mr. David Flint, of Mann, Judd, Gordon and Co., 142 St. Vincent Street, Glasgow, C.2.

Imperial College of Science and Technology, London: Report for the Year 1952-53

THE Government announced, on January 29, 1953, that it intends to provide for the major expansion of the Imperial College of Science and Technology, London, and commenting on this the governing body of the College, in its forty-sixth annual report for the year ended July 31, 1953 (pp. 55; 1953), points out that two aspects have to be considered: first, to decide what is academically most desirable; and secondly, to devise an architectural plan designed to provide the necessary academic facilities, largely by building on land at present used by other institutions for other purposes, without the knowledge when the land will be available to the College builders. The governing body emphasizes its satisfaction at the Government's decision, and in the meantime records the building of a further extension to the Department of Metallurgy, improvements to the John Farmer (botany) building for the Department of Plant Physiology, and the purchase of a further 93 acres of land for the Field Station at Silwood Park, Sunninghill, and of the vacant site at 184 Queen's Gate, London, S.W.7. In view of the success of the lunch-time functions organized to encourage general studies in the College, the experiment is being continued for a further year, as is the joint experiment with the London School of Economics in arranging joint postgraduate studies in technology, economics and administration. Of the 1,653 full-time students (only 47 women), 114 came from foreign countries, 198 from Commonwealth countries outside the

British Isles, and 538 from the British Isles outside a radius of thirty miles from the College. The accumulated excess of expenditure over income has been reduced from £19,152 to £1,458. The usual valuable list of published papers, arranged departmentally, is appended to the report.

Use of Aircraft in Agriculture

In 1952 the Food and Agriculture Committee of the Organization for European Economic Co-operation sponsored a mission to the United States to study the use of aircraft in agriculture, with the view of promoting its development in Western Europe. From its report (Technical Assistance Mission No. 107; O.E.E.C., 2 rue André-Pascal, Paris 16^e) it is evident that great advances in this technique have been made since the Second World War, largely owing to the discovery of new synthetic insecticides and weed-killers suitable for low-volume application, and the availability of adaptable war-surplus aeroplanes. In the United States some seven thousand aircraft, compared with sixty-five in Western Europe, are now in use, chiefly for pest and disease control, seeding and fertilizing. While it is recognized that conditions in Europe, where intensive agriculture prevails, are not entirely comparable with those in the United States, the Committee nevertheless considers that there is great scope for expansion in the use of agricultural aviation both in Western Europe, North Africa and other overseas territories. To put the matter on a sound international basis, it recommends the establishment of a European Agricultural Aviation Centre (possibly under the aegis of the Organization for European Economic Co-operation and the European Plant Protection Organization) and the formation of an association of agricultural air companies to facilitate the exchange of technical information, safeguard standards and promote research. In addition to describing the current uses of aircraft in agriculture in the United States, the report includes sections on the economic, technical and operational aspects of the subject.

Fusarium Studies

In a study of the antagonism of soil micro-organisms, including a considerable number of bacteria and actinomycetes, to *Fusarium oxysporum* f. *lini*, a pathogen causing wilt of cultivated flax, R.-O. Lachance and C. Perrault (*Canad. J. Bot.*, 31, 5, 515; 1953) found that nineteen bacteria and eleven actinomycetes showed some antagonism; of eleven organisms which yielded large inhibition zones on agar plates, six had a fungicidal and five a fungistatic action on the *Fusarium* conidia. Among the nineteen antagonistic bacteria under trial, six induced a swelling of the germ tubes or the production of an appressorium-like structure on agar. Greenhouse experiments have indicated that fifteen bacteria and eleven actinomycetes offered a certain protection to seedlings, some of which reached 6, 12, and sometimes 24 in. in height before showing any signs of wilting. The organisms evidently delayed the onset of wilt symptoms, but failed to protect the plants through their entire growth. R. H. Storer (*ibid.*, p. 693) has reported on the effect of soil moisture on *Fusarium* species. Six species and forms of the genus *Fusarium* show optimum growth and survival in soil at 15 per cent saturation. Optimum soil moisture content for actinomycete growth and survival is similar to that for the *Fusarium* species, whereas that for bacteria is at 75 per cent soil

saturation. The present studies indicate that *Fusarium* spp. are strongly aerobic and that *Fusarium* populations can be greatly reduced by maintaining the soil in a saturated condition in the absence of hosts.

Salt-uptake by Root Tissue Cytoplasm

The relation between the uptake of salt by root tissue, that is, by the cytoplasm, and the external concentration of the salt, has been investigated in some of its biophysical aspects by A. B. Hope (*Austral. J. Biol. Sci.*, 6, 396; 1953). The proportion of a given length of bean-root tissue which appears to reach the external concentration when placed in potassium chloride solutions (the apparent free space) increases as the external concentration is increased. The experimentally determined values of the apparent free space at various concentrations of the medium fit the curves representing the quantitative relations between apparent free space and the external concentration deduced by assuming a Donnan equilibrium between the root cell cytoplasm and the medium at each concentration. Thus the experiments indicate the presence of non-mobile ions (probably anions) in the cytoplasmic phase. The concentration of these ions has been calculated to be of the order of 0.01 mol./l. for both bean and maize root cytoplasm. Mature cells seem to have a higher concentration than those less mature. The relation between uptake of potassium chloride by bean-root sections and the time of immersion has been found to follow Fick's law of diffusion. The apparent coefficient of diffusion for potassium chloride in the tissue has been calculated. A typical figure is 0.07×10^{-5} cm.² sec.⁻¹, about one-twentieth of the value for an aqueous solution for the same concentration. The results of these experiments are discussed in relation to the few existing evaluations by other investigators of the non-mobile ion content of cell cytoplasm.

Bibliography of Natural History

The Society for the Bibliography of Natural History (c/o The British Museum (Natural History), London, S.W.7) is a scientific society instituted for the study of the bibliography of all branches of zoology, botany and geology. The Society publishes a *Journal* containing collected lists of bibliographical papers already published on various branches of natural history; original contributions in regard to the dates of publication of zoological, geological and botanical works; particulars relating to the disposal of the libraries and collections of deceased naturalists; and papers on bibliographical subjects. It is proposed also to publish from time to time in the *Journal* facsimile reproductions of rare or unique works or parts of works on natural history.

Effect of Movement of Surface Masses on the Rotation of the Earth

In a paper on "The Effect of the Movement of Surface Masses on the Rotation of the Earth" (*Mon. Not. Roy. Astro. Soc., Geophys. Supp.*, 6, 8; 1953), Andrew Young refers to the third edition of Sir Harold Jeffreys's "The Earth" (pp. 215-16), where doubt is expressed concerning the validity of the equations of motion governing the variation of latitude. This doubt arises from the view that an observer on the solid surface of the earth cannot observe the changing motion of the whole earth, because the axes fixed in the solid earth do not necessarily continue to coincide with the axes of reference

used in the derived equations. In addition, with the seasonal redistribution of surface masses which gives rise to the forced motion in the variation of latitude, there is associated a seasonal variation of angular momentum relative to the solid earth, and this is responsible for an observable variation in the rate of rotation. Mr. Young shows that in the investigation of the effect of surface mass movements on the general rotation of the earth, the change in the length of the day may be treated independently of the variation of latitude. In addition, the seasonal variation of latitude can be described by the usual equations, but account may have to be taken of corrections for the angular momentum of the surface masses. He derives equations which are based on the assumption of axes of reference fixed in the solid earth, and hence fixed relative to an observer on the solid earth, which disposes of the doubt expressed by Sir Harold. It is claimed that the equations remain valid for secular changes in mass distribution over periods of decades; but for periods of centuries some modifications in the equations may be necessary.

Geological Museum, London

THE Geological Museum in South Kensington has now been opened to the public for ten years—four before the Second World War and six years since. It was thus appropriate that in the February number of the *Museum Journal* Mr. A. J. Butler, assistant curator, should give a brief critical commentary based on experience gained during these years. Attendance at the Museum has risen progressively since the end of the War. Though the Museum is visited by specialized groups of the community, it is estimated that about a quarter of a million went for diverse casual reasons. The success of the regional policy in exhibition is now assured, while the geological globe, the gemstones exhibit and the illuminated geological column are always centres of attraction. Mr. Butler is definitely of the opinion that the well-known dioramas have fully justified their initial outlay. He feels, however, that although the exhibits are arranged on a systematic plan, few visitors follow this but wander from one point to another according to the object which happens to hold their fancy.

Index for 1921-50 of the *Physical Review*

THE original intention of the American Physical Society was to publish a cumulative index to the *Physical Review* every tenth year; but this has never been realized. The first index covered the period from the first issue of the journal in 1893 to 1920. In 1930 the world depression, and in 1940 the Second World War, prevented further publications. However, with the financial assistance of the Office of Naval Research and under the direction of Prof. J. W. Buchta, a cumulative index covering the thirty-year period 1921-50 has now been compiled. It is published in two volumes, an author index of 543 pages and a subject index of 498 pages. Prof. Buchta is the present editor of the *Reviews of Modern Physics*; but during the period covered by the index he was assistant editor of the *Physical Review*.

Library Classifications

IN a letter commenting upon Prof. Purchon's communication (see *Nature*, 172, 940; 1953) on library classification, which he thinks expresses the disappointment felt by others with the Library of Congress Classification, and the Universal Decimal

Classification, Mr. Faquir Chand, of the Department of Library Science, University of Delhi, directs attention to the Colon Classification invented by Prof. S. R. Ranganathan. Mr. Chand points out that during the past ten years Ranganathan and his co-workers in India and Great Britain have evolved several helpful concepts and techniques which have made such classification sufficiently resilient to accommodate new knowledge without disturbing the sequence among old knowledge. The fourth edition of Ranganathan's book "Colon Classification" was published by the Madras Library Association in 1952, and Mr. Chand states that a new quarterly periodical, *Annals of Library Science*, will be published to communicate the findings of the Library Research Circle at Delhi, which is constantly engaged in giving effect to the new concepts and in improving the new techniques.

Statistics and Personnel Management

A PAPER on "Statistics and Personnel Management" was given by Prof. M. G. Kendall at the national conference of the Institute of Personnel Management in Harrogate during October last year, and it has now been published by the Institute (Occasional Paper No. 8; pp. 16; London, 1953; 3s.). It is an unexpectedly sprightly and general account of the subject, for Prof. Kendall has managed in the space of sixteen pages to make clear, if not to define, the essential nature of the statistical method in social applications, to state Pareto's Law and apply it illustratively to a question of wage-fixing, and to indicate ways in which statistics might, and perhaps should, be used in other managerial problems. The pamphlet forms useful reading for sixth forms of schools or first-year economics students.

National Science Foundation: Grants

THE award of a second group of grants during the fiscal year 1954 for the support of basic research and related matters has been announced by the National Science Foundation, Washington, D.C. The grants are a hundred in number and total about 1,045,000 dollars, their purpose being for research in the biological and the physical sciences, and for the support of studies and conferences on science, scientific information exchange, compilation of scientific personnel information, education in the sciences, and travel of American scientists to international scientific meetings. The awards for research are for work in the following fields: astronomy, chemistry, developmental biology, earth sciences, environmental biology, engineering sciences, mathematical sciences, molecular biology, physics, psychobiology, regulatory biology and systematic biology. Tenure of the grants ranges from one to five years, with an average length of 2.2 years.

Physical Society's Handbook of Scientific Instruments and Apparatus

THE Physical Society's exhibition at the Imperial College of Science and Technology (Imperial Institute Road, London, S.W.7) is now a firmly established 'hardy annual' of London's scientific life, the recorded attendance last year being more than twenty thousand, and equally established and an essential requisite for all those who intend to visit the exhibition this year (to be held during April 8-13) is the Society's "Handbook of Scientific Instruments and Apparatus, 1954" (pp. 201+pp. 76 advertisements; from the Society, 1 Lowther Gardens, Prince

Consort Road, London, S.W.7; 6s., or 7s. 3d. by post). But the value of the handbook is not limited to those who will have an opportunity of seeing the exhibition, for within its two hundred-odd pages are to be found a selected account of British instruments and apparatus and scientific and technical books that will serve as a valuable reference work to all those concerned with the physical sciences and technology. The book is arranged in numerical order of stands at the exhibition, and short paragraphs describe each particular item. There are an index of exhibitors' names and a fairly detailed subject index which supply all that is needed to locate any entry. Because of the restriction of exhibition space this year, the Society has been forced to limit severely the number of firms and establishments which it could invite to participate, and in order to compensate for this in some measure a new section of the handbook has been instituted in which firms describe items that would have been exhibited had space been available; this section, which consists of twenty-nine pages, is printed on yellow paper to distinguish it from the other items.

University of London: Appointments

THE following have been appointed to readerships tenable at the Royal Free Hospital School of Medicine, University of London: Dr. D. N. Baron (chemical pathology), formerly senior lecturer in clinical biochemistry in the Middlesex Hospital Medical School, London; Dr. Eleanor J. Zeimis (pharmacology), formerly lecturer in pharmacology in the School of Pharmacy, London. Dr. P. Du Val, formerly senior lecturer in the University of Bristol, has been appointed to the University readership in geometry tenable at University College, London. The title of reader in mathematics in the University of London has been conferred on Mr. T. V. Davies in respect of the post held by him at King's College, London.

Atomic Energy of Canada, Ltd.: Chalk River

IN *Nature* of January 2, we referred to the Chalk River atomic energy establishment as "a closed community engaged exclusively on secret work". Dr. W. B. Lewis, Vice-President for Research and Development, writes that this is not the case. "Almost all research work at Chalk River in pure nuclear physics and in biology is non-secret and less than half of that in chemistry is secret. It is mainly the technological aspects of the plant which are secret. The scientific staff freely discuss their work with colleagues in universities and other laboratories in America and Europe. Some fifty papers on original work are published annually. Lectures are given at universities and scientific institutions by scientists on the staff, and papers are presented at meetings of learned societies such as the American Physical Society, the Royal Society of Canada and the Chemical Institute of Canada. Visitors from other laboratories may come to Chalk River for discussions of non-secret work, subject only to certain reasonable formalities. General interest visits are not encouraged, but visiting scientists number about forty a month. As in Britain, security clearance is a requirement for all staff, because the disadvantages of splitting the establishment far outweigh the possible advantages. Besides basic research, it should be noted that the principal target of Canada's atomic energy programme is atomic power. Although by British standards this plant is geographically remote, it is not, we feel, intellectually isolated."

Announcements

THE University of Sheffield has conferred the title of reader on the following: Dr. J. G. Boswell (plant physiology), at present senior lecturer in botany; and Dr. E. T. B. Francis (vertebrate zoology), at present senior lecturer in zoology.

DR. R. M. WILLIAMS has been appointed director of the Applied Mathematics Laboratory of the Department of Scientific and Industrial Research, New Zealand, in succession to Mr. I. D. Dick, who was recently appointed an assistant secretary of the Department. Dr. Williams was born in Christchurch, New Zealand, and graduated in mathematics from Canterbury College in 1940. After war work, first on radar and then in the United States on the atom bomb, he obtained a Ph.D. at Cambridge and then, in 1949, took up a post as senior mathematician at the Applied Mathematics Laboratory.

THE new building of the Borough Polytechnic, London, S.E.1, will be open for inspection during April 7-9. This building includes laboratories for pure and applied chemistry, biology and biochemistry.

As a result of war damage, etc., the records of University College, London, were much impaired. The College is now preparing a complete list of those who have studied there either as undergraduates or postgraduates or who have been otherwise associated with the academic work there. The College is therefore asking anyone who has been in any way associated with it to write to the Secretary, giving their present addresses and a short statement of their careers with dates.

THE seventh annual congress of the Laboratory Animals Bureau will be held this year in the University of Sheffield during April 5-6. At the end of the first day the Animal Technicians Association will hold its annual general meeting. Further information can be obtained from the Laboratory Animals Bureau, M.R.C. Laboratories, Holly Hill, London, N.W.3.

THE Universities Federation for Animal Welfare is holding an Easter congress in University College, London (Malet Street, London, W.C.1), during April 6-9. The congress is open to all, whether members of the Federation or not, on payment of a fee of 2s. 6d. Full board (£3 3s., or 30s. for students) is available in the College. Further information can be obtained from Miss M. P. Williams, Branch Organizer of UFAW, 284 Regent's Park Road, London, N.3.

THE Development Commission is offering a few grants to British honours graduates for training in research problems in marine or freshwater science, which is designed to fit them for employment either in the Fishery Research Services of the Ministry of Agriculture and Fisheries and the Scottish Home Department or in a marine or freshwater biological research institute. The grants are worth £250-£350 a year, with extra university fees paid, and are tenable from October 1 initially for one year, but renewable up to a maximum of three years. Application forms, to be returned by May 20, can be obtained from the Secretary, Development Commission, 6a Dean's Yard, Westminster, London, S.W.1.

NOMENCLATURE OF VIRUSES

THERE has been much discussion as to the wisdom of applying to viruses binomial names of the Linnaean type, and in particular as to the advisability of doing this over the whole field and forthwith. At the Fifth International Congress of Microbiology held in Rio de Janeiro in 1950, the International Nomenclature Committee, on the advice of its virus subcommittee, held that an attempt to apply binomials to viruses in a comprehensive way is premature; it suggested what criteria could be used in any attempted classification; further, study groups were set up for certain better-known virus groups with the view of determining whether binomials could profitably be applied to such viruses, as a beginning. Study groups were thus set up for the psittacosis-lymphogranuloma group (Chlamydozoaceae), the pox viruses, insect-pathogenic viruses, the viruses related to influenza and those of the arthropod-borne encephalitides.

At a symposium held in New York in January 1952, this piecemeal 'Rio approach' was generally favoured; and two more study groups were set up for viruses related to poliomyelitis and herpes simplex respectively.

At the Sixth International Congress of Microbiology held in Rome in September 1953, the virus subcommittee of the International Nomenclature Committee considered the whole question, having before it the reports of its study groups. Nine animal virologists and six plant virologists were present at one or both of the meetings held. They decided to reiterate the conclusions of the meeting in 1950 that at present "the use of systems of classification for and the application of binomials to viruses as a whole are undesirable and should be discouraged". They also recommended that the starting date for valid Linnaean nomenclature for viruses should not yet be determined, and that until this was done names for viruses already proposed should have no standing in bacteriological nomenclature.

The subcommittee favoured, with one dissentient, the application of internationally accepted names to all viruses. On the other hand, the plant and animal virologists present, polled separately, voted by majorities against the application of Linnaean binomials to viruses at the present time. The feeling of the majority was that such names necessarily carried implications as to taxonomic relationships, and that sufficient evidence as to such relationships was not yet available.

The animal virologists, at a separate meeting, felt that the use of comprehensive systems of nomenclature such as had been introduced in teaching as well as in the literature¹ would not be discontinued unless something else were offered as a substitute. Use of a Linnaean system at the moment would be particularly unfortunate if it led to an undesirable separation of practice between the animal and plant subsections. Other names were therefore put forward of such a nature that their special character was obvious, yet they could later be transferred to the Linnaean system under the International Code. Grouping of viruses should at present start at the generic level (or equivalent).

It was agreed that the report of the Chlamydozoaceae study group should be accepted; this held

that the viruses related to psittacosis were closely related to the rickettsiae and should be considered together with them. This implied their inclusion in Rickettsiales under the bacteriological code and their removal from the sphere of consideration of the virus subcommittee.

A majority vote favoured a uniform system of forming the equivalent of generic names, and rather than forming these from personal names (eponyms), favoured the use of the suffix '-virus' as shown in the appended list. Such a suffix would mark these names as being something apart from the Linnaean system but need not involve change in names if the Linnaean system were later applied to viruses. Names with the '-virus' suffix should be of the neuter gender. Though the names of viruses would be binomials, the terms 'genus' and 'species' would be avoided at present; the terms 'group' and 'group-member' or similar designation being used instead. Such names should, however, be printed in italics in scientific papers, as with Linnaean names, and capital letters would be used for group names. The names would not, however, be ascribed to authors, as under the Linnaean system, and the law of priority would not be applied at the present time. In order, therefore, to avoid confusion, the names under this system should be officially sanctioned by the International Nomenclature Committee or its virus subcommittee. The equivalent of type species should not be designated, but type strains should be deposited with appropriate collections of type cultures. Names in the appended list would be the first to receive such official sanction. The list of approved names of group members should be added to and revised from time to time. Publication of lists of newly approved names should be in the *International Bulletin of Bacteriological Nomenclature and Taxonomy*; but full descriptions of viruses the names of which were approved should be published in other appropriate scientific journals by specialists concerned, with the approval of the virus subcommittee.

The plant virologists, rejoining the discussions, concurred with the principles just outlined, though not committing themselves to the use of the '-virus' suffix or any particular form of 'group' name in their field. Dr. L. M. Black, chairman of the plant virus subsection of the virus subcommittee, was unable to be present; he had not been able to present a report likely to command any general acceptance among plant virologists. Dr. J. Craigie, for the bacteriophage subsection, had submitted a unanimous report which maintained that Linnaean binomials could not at present be suitably applied in the phage field. Of the animal virus study groups, that considering arthropod-borne encephalitides felt that relationships within the group were at present so uncertain that application of binomial nomenclature was premature. Names were agreed to for viruses of the pox, influenza, insect-pathogenic, poliomyelitis and herpes subgroups, based on reports of the various study groups and, in some instances, modified by the main virus subcommittee.

It appeared that plant virologists were much more evenly divided concerning the use of Linnaean binomials than were animal virologists. The use of the '-virus' suffix is proposed now only for animal

viruses. The subcommittee was strongly against any course of action which would prejudice future chances of a common policy for the nomenclature of all viruses, especially now that some viruses have been shown to multiply both in plants and insects. It thought that its recommendation embodied useful positive proposals for animal viruses, and yet did not compromise future parallel action with plant virologists.

A report embodying these conclusions was presented to the main International Nomenclature Committee, which approved its publication in the *International Bulletin of Bacteriological Nomenclature and Taxonomy*. This explanatory note is written in the belief that as wide publicity as possible for the recommendations is desirable.

PROPOSED "NON-LINNAEAN" BINOMIALS FOR SOME ANIMAL VIRUSES

<i>Poxvirus variolae</i>	(smallpox)
" <i>officinalis</i>	(variola)
" <i>bovis</i>	(cow-pox)
" <i>muris</i>	(ectromella, mouse-pox)
" <i>avian</i>	(fowlpox)
" <i>mollium</i>	(molluscum contagiosum)
" <i>myxomatidis</i>	(rabbit myxoma)
<i>Herpesvirus hominis</i>	(herpes simplex)
" <i>zoster</i>	(pseudorabies)
" <i>stuebs</i>	(B virus)

The group name *Myxovirus* for viruses related to influenza was intended to indicate that the viruses in question have a particular kind of affinity for certain mucins.

INSECT-PATHOGENIC VIRUSES

Poliovirus (= *Borrelia*): group members are *P. boumbyi*, *effluens*, *reprensus*, *olearius*, *compesens*, *perceptor*, *fasciiformis*.
Ompovirus (= *Bergoidia*): group members are *O. calypsum*, *ambolus*, *halicticus*, *thompsoni*, *oleorhabdus*, *brassicae* and *noctodes*.
Globovirus (= *Smithia*) *rotundum*.
Morovirus (= *Morator*) *nashum*.

All the names of group members among insect pathogenic viruses correspond to the specific names listed by Bergold¹ and Steinhaus².

RADIATION HAZARDS OF ATOMIC ENERGY*

A POWER programme on which a nation's economy rests inevitably has its hazards. Coal-mining is a dangerous occupation; drilling for oil and refining is subject to fire risk. Releasing energy from the atomic nucleus has its own particular dangers, notably from ionizing radiation, and the atomic-energy industry of the future will have to be planned to avoid these hazards. The cost of

safety devices will be great, and it will be the business of statesmen to decide how to balance the economic price of safety against the hazards to health.

Experience with ionizing radiations began more than fifty years ago with the discovery of X-rays and radioactivity. Many of the early investigators fell victim to burns, diseases of the blood and blood-forming organs, and cancer. In 1921 the X-ray and Radium Protection Committee was formed in Great Britain which set national standards of safety. This task has now been taken over by the International Committee on Radiological Protection.

Originally the safety of only a few hundred experimenters had to be considered; but now it is a problem of hundreds of thousands within the atomic-energy industry, and of the population at large. There are two main hazards to consider: those from electromagnetic and corpuscular radiations applied from without, and from radioactive materials taken into the organism.

Nuclear reactors must be enclosed within biological shields to absorb the γ -rays and neutrons. The re-processing of enfeebled reactor fuels and the extraction of plutonium and fission products must be carried out in a way which will minimize the escape of radioactive materials to the atmosphere or in drains. It is impossible, however, to prevent such escape completely and one must budget for a certain liberation of radioactive elements in routine operation, in addition to possible accidents. The question then is what is the radiation dose that can be tolerated.

All ionizing radiation is harmful to living tissue. Nevertheless, evolution has occurred in the presence of a natural background of radiation from cosmic and terrestrial sources, which produce a total dose of about 100 milli-roentgens per year. On the other hand, it is known that large doses have caused death and disease among scientific workers, luminous dial painters and miners in the Schneeberg; these effects can be reproduced by irradiating animals. In addition, radiation can induce unfavourable mutations. Little is known of the effects of radiation in human genetics and one has to infer from genetic investigations on the lower forms of life, where reproduction is rapid, such as the *Drosophila* or the mouse. The phenomenon of increased mutation-rates might be the limiting factor in the ultimate development of atomic power. What one can do at the moment, when still only a small fraction of the population is at risk, is to see that the national population dose of radiation released by man (the product of average dose of those occupationally exposed and the total number exposed) does not significantly exceed the national population dose from natural radiation. This is a form of compromise adopted in establishing the maximum permissible dose, which usually is about one-tenth of the minimum damaging dose to man or experimental animal. Where this is unknown it is calculated from biological or physical data and extra safety factors are added.

One of the main problems is the disposal of fission products. Some can be concentrated to a small volume and made insoluble in water and stored underground or under water until they decay. A small fraction, however, will inevitably escape into the air or into drains, preferably direct to the sea, where the activity will be greatly diluted. If the energy equivalent to the present total coal consumption in Great Britain were obtained from fission, the total activity of, say, strontium-90 would amount to

* Summary of a lecture by Dr. J. F. Loutit, being the fourth of the series of public lectures arranged by the Atomic Scientists' Association and the Department of Extra-Mural Studies of the University of London (see also *Nature*, February 27, p. 386, March 13, p. 477, and March 27, p. 573).

8,500 megacuries. If this were 1 per cent of the world's effluent and it all became uniformly mixed in the sea (of a total volume 1.4×10^{24} c.c.), the concentration would be 6×10^{-7} microcuries per c.c., which is about the permissible activity for drinking water. The sea already contains 3×10^4 megacuries in the form of radioactive potassium, hence there should be no danger if the active effluent is uniformly mixed. Unfortunately, mixing in the sea is subject to weather conditions and there may be 'hot' spots of dangerous activity.

The biological hazards from the fission products depend largely on their chemical and physical states. Iodine, for example, is very important biologically because of its concentration in the thyroid; but it is not a serious problem in routine operations as it decays in a short time. In accidents or bombs, however, it may become a danger if it is deposited in the fall-out. In the Monte Bello test the fall-out contained water-soluble iodine, which was taken up in the thyroid of guinea pigs.

Of the other fission products, caesium behaves like sodium; it is difficult to precipitate and would be expected to be found in water effluent. Tests for its presence in seaweed are being carried out. Barium and strontium, which are relatively soluble, are deposited in bone. The other elements are relatively insoluble in water or the digestive tract, but may be deposited on the lining of the gut.

The activity ingested by domestic animals is also of importance. The fresh vegetable diet consumed by man is small and its radioactivity has a chance to decay in storage. Animals, however, eat large quantities of grass, and superficial contamination of the earth presents an internal hazard to the animal and, consequently, to man eating the meat. The safeguard is again the time factor, and that most of the activity is deposited in bone.

Man receives a relatively larger intake through the lungs than through the alimentary tract. Most of the particles are, however, large enough to be caught up in the filter system of the upper respiratory tract, from which they are finally conveyed to the gut. The most important thing, therefore, is to keep the air clean and uncontaminated. Clean air ensures clean soil, vegetation and water supplies. Use of the sea as a disposal ground must be controlled to avoid contamination of edible fish. The ocean depths may be a suitable dump for concentrated sources until technical improvements in propulsion make it possible to discharge them to interplanetary space.

UNESCO ADVISORY COMMITTEE ON ARID ZONE RESEARCH

SESSION IN MONTPELLIER

THE Advisory Committee on Arid Zone Research, which is a Committee of the United Nations Educational, Scientific and Cultural Organization, held its sixth session in Montpellier during November 3-8, 1953, and the following are the principal recommendations that were made to the Director-General of Unesco.

Symposia. The holding of symposia should be continued, and, when possible, half of them should be jointly organized with other relevant agencies or

scientific organizations so as to achieve closer liaison with them. The Director-General, it is suggested, should accept the invitation of the Indian Government to hold a symposium on "Wind and Solar Energy in Arid Areas" this autumn. Also, the subject for the symposium to be held in 1956 should be the formation and erosion of soils as affected by climatic factors, and this should, if possible, be held jointly with the Food and Agriculture Organization and the World Health Organization.

Review reports. It was decided at the session that review reports should be fewer in number and that they should deal with research subjects rather than consist of surveys of specific geographical areas. Each report ought to be a critical appreciation of work done and not merely a summary of publications. The reports should be published in book form, and, when a symposium is held on the same subject, they should be published, if possible, with its proceedings. The recommendation was made that six reports be obtained dealing with human and animal ecology in arid regions, two being on human ecology and one each on the ecology of mammals, birds, locusts and other insects.

Arid zone fellowships. Candidates selected for such fellowships should be of sufficient seniority and training to obtain adequate benefit, and careful consideration must be given not only as to the best location for the Fellow to work but also as to the person responsible for his studies and the length of his stay in each locality. Each Fellow should submit both interim and final reports on his work to the Committee.

Research projects. The Committee recommended the following procedure to be adopted in the submission of research projects to Unesco, and for their consideration by the Committee. (1) Projects should be submitted after examination by, and with the support of, the national commission of the member State from which it originates. Information should be provided about the suitability of the applicant to conduct or supervise the work, and where relevant as to the relation of the project to other research. If the applicant is a member of a scientific institute, this institute should also give its support. (2) If it feels this desirable, Unesco should obtain further expert advice on the project from among its honorary consultants prior to submitting the proposal to the Advisory Committee. (3) Recipients of Unesco research grants must submit by March 1 and September 1 progress reports for the information of the Advisory Committee. Failure to submit such reports may involve the discontinuance of Unesco support. (4) The Advisory Committee should review current projects and should consider whether to advise continued support for them, before giving advice on the support of new projects.

The Committee also recommended that three criteria should guide the acceptance of projects submitted: the project must directly relate to a specific arid zone problem; it should bear on some principle of general scientific interest; and it should either be of a nature that can be expected to yield results within a period of two years, or be one that can be continued by local support, after initial financial aid from Unesco.

Unesco Symposium of Plant Ecology of the Arid Zone. Following the session of the Committee, a symposium organized by Unesco as part of its arid

zone programme was held during November 7-10 in Montpellier with the help and support of the university there. Speakers from fifteen countries contributed papers under the following sections. (A) Structural and physiological features of the vegetation. This section included papers on ecological classification, the fodder value of desert plants in South Africa, and the effects of land management on arid zone vegetation. (B) Climatic, ecoclimatic and hydrological effects on vegetation. The papers in this section dealt not only with effects of rain and other climatic factors but also with dew measurement and with forests in arid areas. (C) Soil and vegetation. This section covered the effects of soil type, the influence of minor elements and soil microbiology. (D) Influence of other factors. These included overgrazing and soil insects, and a valuable account was given of methods used in Australia in land-use surveys. The symposium as a whole included a number of valuable papers and provoked keen discussion. Its proceedings will be published.

NEW CHEMICAL LABORATORIES OF THE UNIVERSITY OF SHEFFIELD

THE new chemical laboratories of the University of Sheffield were opened on February 5 by the Earl of Scarborough, and afterwards honorary degrees were conferred upon Sir Cyril N. Hinshelwood, Prof. O. K. Ingold and Mr. T. A. McKenna. A single structure now takes the place of laboratories that were formerly separated from one another and from the central stores by a hundred yards horizontally

and as many feet vertically in a building without lifts. While the greater part of the cost has been met by grants to the University for that purpose by the University Grants Committee, the Staveley Coal and Iron and the Staveley Iron and Chemical Companies, in response to the appeal for a University Development Fund in 1947, covenanted to contribute a sum of £50,000 primarily for the benefit of the Chemistry Department. In permanent record of the University's appreciation, the research laboratories in the new Department have been named the Staveley Laboratories.

As the first stage of a larger structure which will be necessary for any significant increase in the present number of students, it consists of a main block facing Brook Hill, with a wing at its eastern end receding obliquely from the street. Provision has been made for additions when necessary at both ends of the block. The four-story building is of steel-framed brick faced with Portland stone; the sloping site allows unrestricted natural lighting to the lowest floor of the wing. The wing consists essentially of four large teaching laboratories, one above the other. From the lowest floor upwards, they are for intermediate classes, advanced inorganic chemistry, physical chemistry and elementary organic chemistry, respectively; each is served by a sub-store connected to the main store by a goods lift. These teaching laboratories have small rooms attached for special purposes, and in addition there are eight research laboratories and seven small rooms for lecturers.

The various floors are united by staircases at each end of the main block and an emergency staircase at the far end of the wing. There is a passenger lift at the junction of the main block and the wing, and provision has been made for another lift at the west end. The junction of the wing and main block, with

New Chemical Laboratories of the University of Sheffield

its lifts and staircase, thus constitutes the main distributory channel for the whole building.

On the lower ground floor of the main block are the central stores, with goods entrance and unpacking area, and separate accommodation for dangerous or excisable materials; here also are the mechanics' workshop, glass-blowers' room, analytical preparation room and micro-analytical laboratory, a laboratory for heavier equipment, and the electrical sub-station and calorifiers serving the building. A basement provides further storage facilities, a constant-temperature room, refrigeration room, and rooms for special equipment.

The main entrance is to the ground floor, which has common-rooms for teaching and laboratory staff and for research students, cloak-rooms, X-ray and spectroscopic laboratories, and the main lecture theatre, which seats 250. This theatre, more than large enough for present departmental needs, is intended to be used also for general university purposes. At the very fully equipped lecture bench are controls governing the window blinds (in sections), the room lighting (in sections), blackboard movement and lighting, and spotlighting of the bench itself. The projection box, in communication with the bench, has 35-mm. and 16-mm. projectors, microfilm projector, lantern and epidiascope.

The Wynne Library, built out from the western end of the ground floor, has been equipped with steel shelving calculated to cope with the menacing expansion of chemical literature for some ten years. It is named in commemoration of the great services to the University of the third professor of chemistry, the late William Palmer Wynne.

Whereas in the completed building the first floor will be entirely devoted to physical chemistry, three of the seven research laboratories in the main block are at present used for organic chemical research. There are also on this floor a reader's room, dark rooms and other small rooms for special purposes, and a lecture theatre with seating for 120. On the second floor of the main block are the professor's room, a reader's room, lecturer's room, four research laboratories, small rooms for special work, a teaching laboratory for advanced organic chemistry, and a small lecture theatre seating 60. Rooms for solvent recovery and for conducting dangerous operations are provided on the extensive flat roof.

As a whole, the building provides working places for some 240 undergraduates at any one time, and, including the teaching staff, for 50-60 research workers. Accommodation for the more elementary classes is multiplied by duplication or triplication of lockers, so that places can be found for as many as 450 undergraduates.

The services in the laboratories include high- and low-pressure cold water, hot water, gas, electricity, steam and compressed air, all carried in readily accessible channels 10 ft. apart, running vertically and horizontally. In addition to the ordinary a.c. supply at 240 V., three-phase current is available at certain points, and d.c. supply is from mobile rectifiers and batteries. Lighting is in general by tungsten lamps in corridors and lecture theatres, but by fluorescent strip, sometimes of 'colour-matching' type, in teaching and research laboratories. Ventilation is by window and by extractor fans—one for each fume cupboard—which work from the roof. The building is heated by hot water provided from the main University station across Winter Street, operating through panels in the walls.

AN ATLAS OF END-GRAIN PHOTOMICROGRAPHS FOR THE IDENTIFICATION OF HARDWOODS

AS the number of hardwood timbers from tropical countries now being placed on the market increases, their identification has become increasingly difficult. The Forest Products Research Laboratory, Princes Risborough, has already produced Bulletin No. 25, "Identification of Hardwoods: A Lens Key", which provides a practical method of timber identification for those lacking laboratory facilities—in other words, for the man out in the forest or in the timber yard. It may not be generally known that, among tropical timbers at least, there may be a close resemblance between a timber of considerable value for structural and other purposes, for example, and another, or more than one, which is of an inferior quality. The fact that the latter exists in greater abundance in the forests and therefore is of easier and cheaper extraction can lead to substitutions which are far from desirable.

The "Lens Key" was prepared for the use of the practical man engaged in the extraction and marketing of these more or less new tropical timbers. To indicate its value to the forest man, an illustration may be given. Whenever possible, water transit is the cheapest and easiest for the transport of heavy timber materials. The felled trees after topping are made up into great rafts and floated down the river until they reach the port or checking station. One or more of the rafts may purport to be of the valuable species of timber of the region. Yet it is simple to include a number of logs of the inferior species, the whole raft being passed for payment on the higher royalty scale. Armed with the "Lens Key", the checking officer is in a position to stop this kind of thing.

The Forest Products Research Laboratory has now produced an addition to the "Lens Key" which can be used in conjunction with it. Bulletin No. 26, entitled "An Atlas of End-Grain Photomicrographs for the Identification of Hardwoods", supplements the "Lens Key" by providing photomicrographs of the timbers dealt with in the latter and enables users to verify their identifications by comparison with photographs of authentic species. As the author says: "it provides a ready means of checking that a timber is what it is reputed to be". Of course, it is to be understood that the user of the "Atlas" must be able to prepare a cleanly cut end-grain surface of the timber in question. A safety-razor blade can be used for the purpose, as it gives a sharper and cleaner cut than a knife.

There are 396 photomicrographs, all beautifully clear reproductions, in the "Atlas" at a $\times 10$ magnification which shows the structure of the timbers dealt with. The arrangement of the photomicrographs according to alphabetical order of botanical families, and within each family similarly according to the botanical names of the timber, is exactly parallel with that adopted for the descriptions of the timbers in Bulletin No. 25. An index giving botanical and common names of the timbers is appended.

KODAIKANAL OBSERVATORY ANNUAL REPORTS FOR 1951 AND 1952

THE annual reports of the Kodaikanal Observatory for the years 1951 and 1952*, both of which have only recently been received, deal mainly with the astronomical work of the Observatory; the meteorological data appear in the *India Weather Review* and the administrative details are to be incorporated in the annual report of the India Meteorological Department. The golden jubilee of the Observatory was celebrated in September 1951, and the event was marked by the inauguration of the newly built Ionospheric Laboratory and of the newly installed 'Bhavnagar Telescope', a 20-in. Cassegrain reflector constructed by Grubb which originally belonged to the now defunct Poona Observatory and named after Maharajah Takhtesinghji of Bhavnagar.

An expedition was organized to observe the total eclipse of the sun on February 25, 1952, and the party of four, led by Dr. A. K. Das, started on December 27, 1951, for the eclipse camp at Ar Ratawi in Iraq. On this expedition, which is referred to in the 1952 report, the observational programme was unfortunately frustrated by bad weather at the time of the eclipse.

International co-operation, including the exchange of spectroheliograms and photoheliograms with foreign observatories, was maintained as usual (a list of these observatories is given); and the daily broadcasts of 'ursigrammes' relating to solar activity, and to issuing warnings for expected ionospheric and geomagnetic disturbances whenever expected, were continued.

A list of the equipment of the Observatory is given in each report, including (a) astronomical and spectroscopic instruments, (b) magnetic instruments, (c) electronic instruments, (d) workshop machinery, and (e) other instruments, with the names of the different instruments in use. The 1952 list shows one more under (a), one more under (b) and six more under (c) compared with the 1951 list. Weather conditions during 1951 were better than those of the previous year, and those of 1952 were better than the 1951 conditions. There was a considerable decrease in sunspot activity in both years. The number of prominences in 1951 showed a decrease of 15 per cent compared with the number in 1950, but there was an increase in the areas of 7 per cent; this was due to greater prominence activity during the second half of 1951. In 1952, prominence activity as represented by areas showed a decrease of 16 per cent, and the numbers an increase of 23 per cent over the 1951 results.

* Kodaikanal Observatory. Annual Report for the Year 1951: pp. 10, 1952; R. 1. or 1s. 6d. Annual Report for the Year 1952: pp. 12, 1953; As. 12 or 1s. (Delhi: Manager of Publications.)

PREHISTORIC SETTLEMENT PATTERNS IN THE VIRU VALLEY, PERU

THE Viru Valley Project was an intensive survey of one of the smaller irrigated valleys of the Peruvian coast. It was mainly archaeological, but embraced also cultural geography and a study of the modern population, and it was carried out by a number of teams from different North American institutions with the co-operation of Peruvian

scholars. Each institution supported its own team and is publishing the results, but they worked together and shared certain resources supplied by the Viking Fund of New York. The work was done in 1946, when Prof. G. R. Willey was working for the Bureau of American Ethnology. Although publication has been long delayed, some of Prof. Willey's views have influenced publication by his colleagues, so they have not been altogether hidden from students of the subject. Now that his conclusions are published in full as a Bulletin of the Bureau of American Ethnology*, his work forms an exceedingly valuable and interesting contribution to archaeology.

The work is based on what must have been a very strenuous survey of the visible settlement sites in the valley, and descriptions of them, with plans, form a large part of the book. Each of the descriptive sections begins with a summary of the contents, so that the bulk of them need be used for reference only. They are preceded by introductory chapters which define the problem and describe the valley, and are followed first by a summary with conclusions about the actual settlement patterns, and then by a discussion of what can be learned from them about the population and its organization at different stages. Finally, these data are related to what is known of Peru as a whole. The plates, grouped at the end, are a useful addition, but the reproduction of some of them is a trifle 'woolly'.

Among the several useful publications resulting from the Viru Valley Project, this deserves a prominent place. By his fresh and thoughtful approach to his subject, Prof. Willey has made a notable contribution to our understanding of the ancient peoples of Peru. The organizers of the Project were fortunate in being able to select a unit of manageable size to deal with, and one which was sufficiently self-contained to make it possible to observe the effects of outside influences and invasions. Very useful results might be obtained if it were possible to follow their example in other centres of ancient civilization.

PHOTOLYSIS OF POLY METHYL VINYL KETONE: FORMATION OF BLOCK POLYMERS

By J. E. GUILLET and PROF. R. G. W. NORRISH,
F.R.S.

Department of Physical Chemistry, University of Cambridge

THE primary photolysis of aliphatic ketones, both in the gas phase and in solution, has been shown to occur by two simultaneous reactions¹:

Type I, in which two free radicals are formed:

Type II, in which the molecules can split in the α - β position to the carbonyl group to give an olefin and a lower ketone, without the formation of free radicals; for example:

As the temperature is raised from 0° to 100° C., the acetyl radical formed in the first reaction becomes increasingly unstable and decomposes to give a free alkyl radical and carbon monoxide.

The Type I reaction has been used as a source of free radicals for the initiation of vinyl polymerization. For example, acetone has been used as a photosensitizer in the polymerization of a number of vinyl monomers³.

As an extension to this early work, it occurred to us that vinyl polymers containing a carbonyl group would be expected to undergo similar reactions upon irradiation. For example, with poly methyl vinyl ketone, we should expect, schematically:

Both these predictions have been verified. The polymer shows a strong absorption band with its peak at 2900 Å. due to the carbonyl group. Irradiation of solutions in dioxan by light of 3130 Å. caused rapid reaction.

The occurrence of Type I reaction is demonstrated by the formation of carbon monoxide and methane when the reaction is carried out at 80° C., and the fact that aldehyde is formed due to the hydrogenation of the acyl radicals by the solvent.

That Type II reaction occurs as a split in the chain at the bond α - β to the carbonyl group is shown both by a rapid fall of molecular weight, and by the development of the absorption band beginning at 2800 Å., characteristic of the conjugation of the double bond with the ketone carbonyl.

The quantum yield of the Type I reaction is of the order of 0.01, as measured by the rate of formation of carbon monoxide at 80° C., but this must be a lower limit in view of the formation of aldehyde mentioned above.

The occurrence of Type I reaction with poly methyl vinyl ketone, in which free bonds are formed in the polymer chain, immediately suggests the possibility of forming block polymers in which a long chain of one type is grafted to another long chain of a different chemical species.

In order to investigate this possibility, poly methyl vinyl ketone was photolysed in the presence of acrylonitrile monomer. The optical system consisted

of a high-pressure mercury lamp (Siemens Type ME) mounted in front of a large searchlight mirror to give a concentrated beam of light. This was directed on to the reaction cell by two 30-mm. diameter diaphragms 15 cm. apart, using a water-cooled filter composed of 2.0 cm. of a solution containing 180 gm./l. $\text{CoSO}_4 \cdot 7\text{H}_2\text{O}$ and 600 gm./l. $\text{NiSO}_4 \cdot 7\text{H}_2\text{O}$, followed by 4 cm. of a solution containing 2.0 gm./l. potassium hydrogen phthalate to isolate the radiation of 3130 Å. Operating at 1,000 watts, this light system gave an energy flux of 1.1×10^{-3} einsteins an hour across an area of 7.0 sq. cm. as determined by a uranyl oxalate actinometer. The reaction cell was of quartz, 2.0 cm. in length and 3.8 cm. in

diameter; it was attached by a side arm to a bulb which could be used for freezing and degassing the solutions, and could be connected to a high-vacuum line through a tap and ground joint. Poly methyl vinyl ketone was prepared by polymerization of the pure monomer in dioxan solution, using benzoyl peroxide as catalyst; it was isolated by precipitation with diethyl ether, and washed with ether to remove any residual catalyst. It was then re-dissolved in dioxan and isolated by freezing with subsequent removal of the solvent by sublimation under vacuum. Osmotic pressure measurements in methyl ethyl ketone solution gave a molecular weight of 220,000. Acrylonitrile was purified by distillation over ferrous sulphate in a stream of nitrogen, and stored until use in a flask cooled with 'dry ice'-acetone mixture; it was then introduced into the reaction cell using a standard volume in the high-vacuum system.

The ultra-violet absorption spectra of the various reagents are shown in Fig. 1. It will be seen that, using monochromatic radiation of 3130 Å., we are working well within the absorption band of poly methyl vinyl ketone, but outside the absorption limit of solvent and acrylonitrile monomer, which latter cannot, therefore, be contributing to any primary chemical reaction. A preliminary series of experiments in dioxan solution showed that the rate of decrease of intrinsic viscosity was measurably less when the degradation was carried out in the presence

Fig. 1. Ultra-violet absorption spectra. 1, Poly (methyl vinyl ketone), 2.0 g./l. in dioxan; 2, dioxan; 3, acrylonitrile (monomer); 4, filters (combined)

of 4.5 gm./l. acrylonitrile monomer. There was, however, no sign of precipitated polymer even after several hours. If block polymers are formed in this case, it seems probable that the length of the acrylonitrile chains is not sufficient to cause precipitation.

A trial was then made in which 0.200 gm. of poly methyl vinyl ketone was dissolved in 20 ml. pure acrylonitrile monomer. On irradiation there was an immediate appearance of turbidity, and after 4.0 mm. a solid precipitate had formed. This polymer was isolated by freezing, the residual monomer being removed by sublimation under vacuum. A Dumas analysis of the polymer showed it to contain 14.1 per cent nitrogen, which corresponds to 54 per cent acrylonitrile. An identical run in the absence of poly methyl vinyl ketone gave no evidence of polymer formation on irradiation for periods up to 30 min. The intrinsic viscosity of this polymer in dimethyl formamide was 3.8. Using the relationship reported by Houtz⁸ for poly acrylonitrile in this solvent, the molecular weight was calculated to be of the order of 100,000. This corresponds quite well with the molecular weight which would be expected if two poly acrylonitrile chains were formed for each molecule of carbon monoxide formed by the Type I reaction, and allowing for partial depolymerization of poly methyl vinyl ketone by Type II reaction.

The polymer was qualitatively fractionated into three distinct components by the slow addition of dioxan to a 1 per cent solution of the polymer in dimethyl formamide. One fraction, which was precipitated almost immediately, appeared to be largely poly acrylonitrile. A second fraction was obtained which was soluble in mixtures of dioxan and dimethyl formamide containing at least 5 per cent of the latter component but was insoluble in pure dioxan. A third fraction, completely soluble in dioxan, corresponded to the usual degradation product of poly methyl vinyl ketone. It seems likely that the second fraction, which amounts to about a third of the total polymer and contains 75 per cent acrylonitrile, represents the major part of the block polymer formed.

In order to prove that the polymerization of the acrylonitrile monomer was not due to catalyst residues present in the polymer, a sample of pure methyl vinyl ketone was allowed to polymerize at room temperature, in the absence of any catalyst. After several days, about 10 per cent polymerization had taken place. This polymer was isolated by freezing in dioxan in the usual way, and 0.080 gm. was dissolved in 20.0 ml. acrylonitrile monomer and irradiated for 3.0 min. The reaction was immediate, yielding 0.285 gm. of polymer of intrinsic viscosity 4.3 ($M_v = 140,000$). Irradiation of pure acrylonitrile monomer in the absence of poly methyl vinyl ketone gave less than 0.002 gm. polymer. There was no dark reaction at room temperature in either case.

On the basis of these results, it would appear that in the photolysis of poly methyl vinyl ketone free radicals are formed which are capable of initiating the polymerization of acrylonitrile monomer. It seems likely that this leads to the formation of two additional polymeric species—pure poly acrylonitrile initiated by the free methyl radical (or acetyl radical) and a block polymer from the radical formed on the poly methyl vinyl ketone chain.

It is possible that this photochemical method may have further applications in the synthesis of other block polymers.

GENETICS OF VIRULENCE IN INFLUENZA VIRUSES

By SIR MACFARLANE BURNET, F.R.S.,
and PATRICIA E. LIND

Walter and Eliza Hall Institute of Medical Research,
Melbourne

VIRULENCE of a virus or other pathogenic micro-organism may be defined as the capacity to produce lesions or symptoms in a given tissue or host. It is a quantitative, rather than an all-or-nothing, characteristic, and in practice it can only be assessed in terms of the difference in the response of two or more host animals or tissues which receive the same dose of virus, or of the difference resulting in the same host from the introduction of the same dose of two or more different viruses. The fact that influenza viruses of widely different virulence for the mouse can all be readily grown in the chick embryo and, with some necessary reservations, accurately titrated by haemagglutination, makes viruses of this group particularly well suited for studies of virulence. We have been concerned for some time with an effort to analyse the behaviour of virulence when recombination between different virus strains takes place. In several instances the distribution of virulence among the progeny from a 'cross' between highly virulent and non-virulent strains indicates that there are multiple genetic factors involved. This may provide a new approach to the general problem of virulence in animal viruses.

In all of our work we have used the allantoic cavity of the chick embryo for culture and titration

of strains of influenza virus which possessed characteristic degrees of virulence for some other host or tissue. The earliest experiments were concerned with 'neurotropism'—the capacity of a strain to produce fatal encephalitis on intracerebral inoculation in mice. Subsequent recombination experiments were concerned with strains differing in virulence for the chick embryo as judged by the production of hemorrhagic lesions, or for the mouse lung where the criterion is the extent to which the lung is consolidated seven days after a standard intranasal inoculation. Any influenza A virus isolated from a human infection by chick embryo inoculation and adapted to grow freely in the allantoic cavity lacks all three of these types of virulence. In each case strains of high virulence have had to be obtained by continued passage in the appropriate experimental host. Almost any strain can be adapted to produce gross lung lesions in mice; but only two influenza A viruses have given rise to variants capable of producing hemorrhagic lesions in the chick embryo and/or transmissible fatal encephalitis in mice. These are *WS* (England 1933) and *MEL* (Melbourne 1935).

The general experimental method was to produce double infections with two strains which, in addition to dissimilar virulence, had other 'marker' characters that could be used to differentiate them. The product of these double infections was titrated in chick embryos and then re-titrated to obtain a sufficient number of positive fluids at the limiting infective dilution (*LD* fluids). These were then tested for each of the relevant characters. Representative examples of any recombinant types obtained were re-titrated and a second generation of *LD* fluids tested for uniformity of character.

Neuropathogenicity for the Mouse

In the work carried out by Burnet and Lind¹, and by Burnet and Edney², double infections with the neurotropic strain *NWS* and the standard influenza A strain *MEL* were made in the mouse brain. From these mouse brains, viruses were isolated which were *MEL* serologically but had the capacity to induce fatal encephalitis on intracerebral injection in mice. Such strains had an additional character not found with *MEL* in being convertible to the 'indicator phase' by simple heating at 55°. This character is easily checked *in vitro* by testing whether or not the heated virus is inhibited by high dilutions of a suitable mucoid inhibitor. For convenience all fluids were screened for the two *in vitro* characters, serology and convertibility to indicator, those which conformed to the pattern of neurotropic *MEL* strains being called *NM*'s. It was soon found, as noted by Burnet and Edney², that considerable numbers of *NM* strains were of much lower pathogenicity for the mouse than expected. In Fig. 1 are shown the results of a survey of experimental results obtained during Burnet and Edney's work in 1951. For this it was convenient to use the day of death of a mouse inoculated intracerebrally as an index of virulence. The 34 per cent of 257 mice inoculated with *NM* strains which survived fourteen days includes mice which showed definite symptoms around six days and then recovered completely, and a few—nearly all from groups in which most of the other mice died—which were sick and emaciated at the end of the test period. Others comprising about a-third are from groups in which none of the mice showed any symptoms.

Fig. 1. Distribution of times of death from intracerebral inoculation of a standard dose of influenza virus strains. Area in each shaded bar shows percentage of inoculated mice giving the indicated result. 3, 4, etc., death on day shown after inoculation; S, survived 14 days. *NWS SL* + *MEL SL*, stock viruses by the interaction of which *NM* recombinant strains were obtained.

This has been the general type of experience whenever neuropathogenic strains are produced by recombination. A very similar distribution has been found when interaction of the strains *NM* (actively neuropathogenic) and *WS*—(non-pathogenic) took place in the allantoic cavity. Here the commonest type of progeny to show the *in vitro* qualities typical of the neurotropic recombinant which we refer to as *N-WSE* was only weakly encephalitogenic. Relatively severe symptoms were produced around the fifth to seventh day after inoculation of the standard dose of a fifth of one hemagglutinating unit, but nearly all symptoms had vanished by the fourteenth day. Other fluids of *N-WSE* character *in vitro* produced fatal encephalitis, while some gave no symptoms.

Pathogenicity for the Chick Embryo with Hemorrhagic Lesions

In the course of many experiments with the systems *MEL/WS* and the primary recombinants *M+*/*WS*—²⁻⁴, records were made of the embryo pathogenicity of large numbers of each *in vitro* type. In Fig. 2 the results are depicted in terms of the percentage of inoculated embryos showing lesions of each of four arbitrarily graded levels of severity.

It will be seen that *MEL*, neither as stock nor as experimentally produced recombinant, ever showed any hemorrhagic power; *WS*—showed a very small proportion of embryos with some lesions. Experimentally obtained *WSE* strains show a wider scatter of activity and a lower mean pathogenicity than stock strains. Recombinant *M+* strains show a similar wide range and include a number in the first bracket which represents failure to produce any

Fig. 2. Distribution of pathogenicity for the chick embryo in original and recombinant strains. Grades 0, I, II, III represent increasing intensity of hemorrhagic lesions in chick embryos inoculated on the chorio-allantois. 'Experimental' fluids are pure clones derived from experiments in which recombination occurred, but include fluids of the same type as the parent forms as well as frank recombinants.

Fig. 3. Distribution of mouse-lung pathogenicity among recombinant types from Influenza A strains. I-IV represent increasing grades of average lung consolidation after administration of a standard dose (1 haemagglutinin unit). The characteristic high virulence of *WS* strains and relatively low and variable virulence of *MEL* strains are unaltered by any of the manipulations.

Fig. 4. Distribution of mouse-lung pathogenicity among recombinant types of Influenza B strains. 0-III represent increasing grades of lung consolidation. Distribution of stock virus (st) clones and of clones from recombination experiments (ex) showing the range of pathogenicity associated with each serological type.

haemorrhagic lesions. It should be stated, however, that all *NM* strains which were tested in six or more embryos have produced some haemorrhagic lesions in at least one embryo.

Mouse Lung Pathogenicity

When *MEL* is 'crossed' with the much more pathogenic *WSE*, the recombinants have the same grade of mouse-lung pathogenicity as corresponds to their serological type—*MEL* relatively low and variable, *WS* high and rarely failing to kill all mice inoculated. No differences could be seen between stock and recombinant types, and in Fig. 3 are shown histograms for the four types as obtained from *MEL/WS* or *M+/WS-* experiments²⁻⁴. It is particularly striking that *WS-* recombinants from *MEL/WS* experiments showed none with any reduction of mouse-lung pathogenicity, nor is there any evidence that *M+* strains deviate significantly from the *MEL* pattern.

With experiments on the influenza B strains *LEE* and *MIL*, the pattern of relatively free distribution of virulence among the recombinants is seen again⁵. *MIL* has no lesion-producing power in the standard dose; *LEE* averages 3+ lesions. In Fig. 4 is shown the distribution of mouse-lung pathogenicity for stock *LEE* and *MIL* strains and for all the experimentally studied *LD* strains from a variety of recombination experiments. This shows very clearly the distribution of a wider range of virulence over progeny of both *MIL* and *LEE* types than is ever observed in the stock strains.

Discussion

In most of the examples which have been mentioned, it is clear that the difference between the

highly virulent and the weakly virulent and non-virulent strain is not a function of a single gene. It is in accord, too, with the well-known gradualness with which virulence of a virus for a new host is built up by passage, suggesting that multiple genetic stages have intervened in the process. The development of virulence by a virus has many points of resemblance to the development of resistance to an antibiotic by a bacterium, and it is particularly interesting to find a similar pattern of results from hybridization of *E. coli* *K₁₂* variants, resistant and non-resistant to chloramphenicol⁶. Some of the loci concerned in these experiments could be located in relation to known biochemical markers but others could not. Cavalli and Maocaro interpreted their results as compatible with the occurrence of successive gene mutations, the genes concerned being largely at least non-allelic. Positive and negative interactions between genes were also postulated.

Recent work by Ada⁷ in this laboratory makes it highly probable that influenza virus A does not contain deoxyribose nucleic acid as a necessary part of its structure. If only ribose nucleic acid is involved in the genetic behaviour, it may well be that the mechanisms concerned are a good deal simpler than those typical of mitosis and meiosis in higher organisms. We have developed what appears to be the simplest available hypothesis to account for the results by postulating the existence of 'virulence genes' rather loosely associated with the rest of the genome. Virulence for tissue *x* is determined by the number of the appropriate virulence genes *V_x* associated with each genome. There is a considerable degree of independence in the multiplication of these units in the host cell, and the average number per genome may be modified by a variety of conditions; and in such instances as we have reported here the units may be distributed between two different types of genome. In none of the examples we have studied does this distribution appear to be a random one. If we regard serological type as the identifying mark of a virus and think of other characters in a recombinant as being transferred from the second parent, then we can speak of relative affinities of different genomes for the postulated 'floating' *V* genes. In the *MIL-LEE* system the *V_x* genes contributed by *LEE* are shared with *MIL*, but *LEE* has either a stronger affinity or loses some of its *V_x*'s with so much difficulty that a random distribution is impossible. There is an indication, too, that in the same system it is sometimes easier to lose all *V_x*'s than to hold a sub-standard number (of the undue number of non-virulent *LEE* strains).

In each of the systems we have studied there is an individuality of behaviour. In the *MEL/WS* system there is no evidence of transferability of mouse-lung virulence whatever. The virulence for the chick embryo characteristic of *WSE* is, however, distributed among two of the four genomes produced (*M+* and *WSE*), but not to *MEL* and only to a very slight extent to *WS-*. If a balance-sheet of *V_x*'s could be constructed, one would expect an overall loss as if *MEL* and *WS-* attracted *V_x*'s away from *M+* and *WSE* without being able to incorporate them. Throughout the work we find a tendency in any types of manipulation in the allantoic cavity to show a loss of virulence—often slight—for other types of host cell. The neuropathogenic strains show this well. When a neuro strain is crossed with a non-neuro strain in the allantoic cavity (whether

intact embryo or de-embryonated egg) it is the rule to find a greatly reduced average mouse pathogenicity. With the *NWS/MEL* system it is easy to obtain *in vitro* *NM's*, but these are mostly of very low mouse virulence. To obtain typical neuro-*MEL* strains from this combination in the chick embryo, it is much more convenient to select them from the first-cycle fluid by sub-inoculating this with anti-*WS* serum on the chorio-allantois and re-isolating strains from the embryo lesions. Similar findings were obtained in experiments with the *N-MEL/WS*- and *N-WSM/WSH* systems*.

When a recombinant that has taken up a new virulence is passaged at limiting infective dilution, most of the *LD* fluids show the same grade of virulence; but where there is change, it is far more frequently to a lower grade, and the occasional rise is always slight.

Further work may make it necessary to postulate a more elaborate genetic mechanism for influenza virus, as Visconti and Delbrück (1953)¹⁹ have done for the *T2* bacterial viruses. At the present time, however, it seems better to look for the simplest possible genetic mechanism that will account for the facts. In view of current thought on the nature of bacterial adaptation and recombination, it may become a valuable stimulus to the interpretation of bacterial genetics if analogies can be drawn from a simpler system such as the influenza viruses as well as from the more complex ones of classical genetic theory.

MORPHOLOGICAL BASIS OF QUALITY IN TEA

By W. WIGHT and P. K. BARUA

Teckla Experimental Station, Indian Tea Association
Scientific Department, Cinnamara, Assam

TEA breeding at this Station was begun by us in 1936 on the recommendation of a commission of inquiry led by Prof. (now Sir Frank) Engledow. Much attention has been paid to the production of tea of the quality which is characteristic of Assam and which can be obtained from no other source. For the purpose of breeding, some character indicative of quality is required.

Progress in this direction can be illustrated by quoting Hunter and Leake¹. These authors reviewed the situation in 1933 in the following words: "The problem of tracing quality back to a character or group of characters, inherent in the plant, and sufficiently definite to form the basis of breeding, is hardly capable of solution. Nevertheless efforts in this direction have been made by Gogh (Cohen Stuart, 1930), who found differences in quality

between pluckings of single trees of a magnitude which could be identified by expert tasters".

Early work by the senior author had disclosed an association between hair on the lower epidermis of the fresh leaf and the quality (as distinct from the particles known as 'tip') of the tea afterwards manufactured. This was recorded in 1936². A greater number of parallel observations was required to establish a general case; these have been obtained during recent years.

We have found pubescence of the tea leaf to be genetically conditioned; and plants which are categorized in respect of hair on one occasion can be expected from experience to remain in substantially the same order. It has been observed that a crude classification of plants into five subjective hair groups by momentarily looking at the lower epidermis of the young leaves gives a significant positive correlation with quality. Even when the hair is estimated once only on a single bush in one season at the rate of 500-1,000 bushes a day, and the shoots from the same bushes are manufactured on an average of four occasions in the next season, a significant correlation is obtained ($r = 0.260$. $P < 0.01$). When hair is estimated with proper replicates, the correlation is found to be much closer.

This is illustrated by data in the accompanying table, which were obtained by assigning numerical indices to four subjective hair groups and by assigning numerical indices to a standard set of six degrees of comparison used by the tea taster in his reports. Seven different progenies were studied, each progeny being obtained from a mating between two clones. Six progenies were repeated as two field plots of twenty-four plants each, and one progeny as one plot of twenty-four plants. The block included two comparable plots of plants raised from a commercial source of seed which is generally recognized as possessing high quality. Samples of the plucked shoots from any one plot were spread uniformly over a shallow dish of standard size, and the amount of hair visually estimated under standard conditions of illumination. The dishes were marked by random numbers, the origin of the sample not being known to the observer. The hair was estimated on five occasions in the early part of the season. In the later part of the season shoots plucked from each one of the nineteen plots were manufactured as a separate sample. Each sample was therefore indicative of the overall quality of all the bushes in a progeny, the quality and hair of all but one of the

Progenies	Mean numerical indices for	
	Hair	Quality
A	0.76	10.0
	0.93	25.0
B	0.68	12.0
	0.96	24.0
C	1.26	47.1
	1.07	40.0
D	1.73	43.8
	1.41	35.7
E	1.73	23.5
	1.81	34.2
F	1.79	24.0
	1.88	24.0
G (check from commercial seed)	1.17	41.4

	2.44	46.1
I	2.59	66.7
	2.96	52.8
J	2.60	56.9

Fig. 1

progenies being determined by two plot repeats. On the first five occasions all the progenies were manufactured, after which the manufacture of the lower quality progenies was successively discontinued to enable other progenies, not relevant to the present argument, to be manufactured; the primary object of the work being to show that progenies considered desirable maintained their quality. The progenies of higher quality and the check were manufactured up to fourteen times from the end of June to early October. The taster received the samples of made tea in tins marked only by random numbers, a different assignment of numbers being used on each occasion. The nineteen pairs of variates obtained from the means of all the observations give a significant coefficient of correlation of 0.76. It is clear that hair can be taken as a reliable index of quality.

Fig. 2

Occurrence of red anthocyanin pigment in the petiole of the leaf is a genetically conditioned characteristic of a distinct type of tea plant which is probably wild in the valley of the Chindwin. This type is not in itself of value and is not cultivated in Assam. It is glabrous and lacks quality. However, the character petiole pigment must have somehow been introduced into pubescent plants which are generally cultivated and where it is now to be seen with varying but always very low frequency and with an intensity of expression much below maximum. General experience shows that, up to some low optimum, pigmentation of the leaf petiole is beneficial to quality; and above this low optimum, pigmentation is detrimental to quality.

In 1947, members of the Association supplied us with samples of seed from more than sixty commercial sources of supply in the important tea regions of north-east India. The characters of the plants raised from the seed sources of a particular region were assumed to be representative of the kind of tea plant generally cultivated in that region. The information obtained from these plants enabled us to construct Figs. 1 and 2 in which the ordinates are proportional to the separate frequencies of plants with a noticeable amount of pigment and plants with maximum hair. Fig. 1 shows a significant but not invariable association between plants with petiole pigment and plants with hair. In Fig. 2 the data are considered by regions, the numerals giving the average 1948-49 export valuation in pies for the region. There is therefore large-scale evidence in favour of the combination of some petiole pigment with hair in a population of tea plants.

Breeding experience, a description of which would be too lengthy to include in this article, supports these conclusions. If a suitable slightly pigmented plant of low quality be mated to a comparatively non-pigmented plant of good quality, then the tea made from the progeny as a whole, in bulk, is no worse than that of the good quality parent and may be better. The pigment disappears in the offspring to all but the experienced eye at the appropriate season. Vigour can be improved by a mating of this nature; and if the vigour is improved then it may be associated with a uniformity among the offspring greater than is usual among cultivated tea plants. The object of tea breeding is to perpetuate favourable parents vegetatively, so as to obtain a permanent source of F_1 seed.

It is necessary to emphasize that successful use of the breeding operations to which we refer here requires considerable experience. The introduction of petiole pigment in sufficient quantity to be noticed by the untrained eye is likely to reduce quality. Typically, petiole pigment is associated with a dominant glabrous condition. It is therefore necessary to introduce the pigment into an F_1 from the comparatively rare combination of some pigment with sufficient hair. Slightly pigmented plants when bred among themselves may produce undesirable segregates. The morphological criteria require more detailed description than is possible in this article, the object of which is to indicate the progress which has been possible in recent years.

We wish to thank the Director, Tooklai Experimental Station, and the Indian Tea Association for permission to publish these results. [Dec. 4.]

Thorium Determination in Deep-Sea Sediments

A METHOD for direct measurement of ionium (thorium-230) has been described in a previous communication¹. Ionium was measured in samples of red clay from the Central Pacific Ocean raised by the Swedish Deep-Sea Expedition (1947-48).

The chemical procedure leads to the isolation, together with ionium, of other thorium isotopes: thorium-227 (Rd-Ac), thorium-228 (Rd-Th) and thorium-232, all α -emitters.

The photographic method permits individual measurement of the activity of these various isotopes: ionium and thorium-232 give only single tracks while a fraction of the disintegrations of Rd-Th and Rd-Ac leads to the production of five-branched stars.

This fraction is a known function of the time of exposure in the emulsion²⁻⁴.

If thorium and Rd-Th are in equilibrium, the number of five-branched stars from Rd-Th is a measure of the thorium-232 concentration.

We can measure with the double emulsion technique⁵ as little as 10^{-6} gm. of thorium, provided it is concentrated in a drop of a few microlitres. Care must be taken to prevent the loss of thoron. Experimental details will be published elsewhere.

Rd-Ac also gives five-branched stars and can interfere in the measurements of Rd-Th. In deep-sea sediments, Rd-Ac can originate from two sources: (1) Rd-Ac in equilibrium with uranium-235. If the uranium concentration is known, it is easy to calculate the correction, which in our samples was always less than 5 per cent (values given by Hecht⁶). (2) Rd-Ac produced by protactinium precipitated in excess from the ocean. Although we do not know the concentration of protactinium in sediments, we have certain criteria to control the source of five-branched stars: (a) rate of growth of the star population with increasing time of exposure in the photographic emulsion; (b) decrease of Rd-Ac (half-life, 10 days), while the Rd-Th remains practically constant (half-life, 1.9 years); (c) presence of the characteristic long α -track of thorium C'; (d) rate of decrease of star activity with depth in the sediment (assuming a rate of sedimentation of 1 mm./1,000 years, any protactinium isolated from uranium-235 must be completely disintegrated below 15 cm. from the top of the sediment).

Thorium has been measured in samples of red clay from the Pacific Ocean. The results are grouped in the accompanying table (col. 4). The concentration of thorium has been calculated from the five-branched star production, assuming thorium to be in equilibrium with Rd-Th and ascribing all the five-branched stars to Rd-Th. Absence of appreciable amount of Rd-Ac stars is proved by length measurement of α -tracks of thorium C' on samples 11 and 12 and by the independence of the number of stars of the depth in the sediment.

The number of samples is not yet sufficient to allow any definite conclusion. Still, we can see that the thorium content does not seem to change appreciably from one sample to another. The figures are grouped around the value 5×10^{-4} gm. Th/gm. dried

THORIUM IN RED CLAY FROM CENTRAL PACIFIC OCEAN. CORES OF THE SWEDISH DEEP-SEA EXPEDITION (1947-48)

red clay. This value is much higher than the figures found by Koczy⁷ in red clay from the Atlantic Ocean. Dr. Koczy has pointed out in a private communication that the difference could be ascribed either to the higher sedimentation-rate prevailing in the Atlantic Ocean, or to incomplete extraction of thorium due to his use of hydrochloric acid extraction instead of dissolution of the samples.

The uranium-content has been measured by Hecht⁸ in other samples from the same cores. He obtains values grouping mostly between 1.5 and 2.5×10^{-4} gm. U/gm. This seems to indicate that in these red clays the thorium-uranium ratio is a little lower, but of the same order of magnitude as the average value in continental rocks.

Chronology of deep-sea sediments by ionium-thorium ratio. Attempts have been made to use the vertical distribution of radium (assumed to be in equilibrium with ionium) for dating back to 350,000 years deep-sea sediments⁹.

This method, which is based on the fact that ionium produced by uranium dissolved in sea-water is precipitated together with the sediments^{1,10,11}, involves some assumptions difficult to check on the rate of precipitation of ionium.

A method based on the ratio ionium-thorium (ratio of two isotopes, one of which is practically stable while the other decays with a half-life of 80,000 years) should be free from this criticism. Such a method would be valid only if: (1) the ionium-thorium ratio in the ocean has remained constant in the time-interval considered (maximum $\sim$ 350,000 years); (2) thorium is precipitated from the sea-water in the same proportion as ionium.

This last hypothesis requires that both ionium and thorium should be dissolved in the same chemical form in sea-water and that all the thorium contained in the sediments should have been chemically precipitated from the sea and not carried in mineral residues.

This hypothesis can be tested by comparing the ionium-thorium ratio in sea-water and in the surface layers of deep-sea sediments or, following a suggestion of H. Pettersson during discussion, by checking if thorium and ionium in the sediments have the same chemical behaviour.

Assuming this condition to be fulfilled, the ionium-thorium ratio in any layer of a sediment column will be found independent of changes, both of the rate of total sedimentation and of the rate of precipitation of thorium and ionium, and should depend only on the time elapsed since the deposition of the layer.

We wish to thank the Oceanographical Institute of Göteborg and the Geological Society of America for financial support. We are indebted to Prof. H. Pettersson and Dr. Koczy for helpful suggestions and to the Misses N. Isaac and G. Poulaert for their

assistance in the chemical separations, and to Prof. G. P. S. Oochialini for useful criticism.

Electron Energy Distribution in the Striated Hydrogen Discharge

THE distribution of energy among the plasma electrons is a factor of primary importance in determining the processes occurring in a discharge. Two matters of special interest in our work are (a) the processes determining the equilibrium of negative ions in electronegative plasmas, and (b) the mechanism of production of atomic hydrogen in discharges in dry and wet hydrogen. In the first, the case of oxygen is well known to be somewhat anomalous in that the negative ion concentration is very much less than it is in the halogen plasmas, although the electron affinity is not vastly different. In case b, the much greater efficiency of radio-frequency discharges for dissociating H_2 and the fact that increased dissociation resulting from an introduction of water vapour does not seem to be entirely attributable to wall poisoning, suggests that the difference between the energy distribution for electrons in a striated positive column and that in the radio-frequency discharge may be concerned in the changed efficiency. The purpose of this communication is to direct attention to some preliminary results for energy distributions in the positive column of a d.c. discharge in hydrogen.

The method employed makes use of the result of Druyvesteyn¹ that for an isotropic distribution the energy distribution function is given by $f(E) = V^{1/2} \frac{d^2 i}{dV^2}$ where i is the current to a Langmuir probe at a potential V with respect to the space. The quantity $\frac{d^2 i}{dV^2}$ may be determined in various ways, namely, by graphical double differentiation; by making $V \propto t$ (time) and evaluating $\frac{d^2 i}{dt^2}$ using resistance capacity circuits²; by the use of a bridge circuit³; and by noting the change in the mean value of i when V has superimposed upon it a small a.c. component⁴.

We have used a development of the last method. When a modulated carrier frequency of voltage is superimposed upon the probe potential, then for small carrier amplitudes the component of modulation frequency in the probe current is proportional to $\frac{d^2 i}{dV^2}$. If, by means of a linear potential divider,

V is now made to vary slowly and a square root law potential divider is varied at the same time by direct coupling, then with the aid of suitable tuned amplifier

circuits the product $V^{1/2} \frac{d^2 i}{dV^2}$ may be continuously

presented on an oscillograph. By means of beam switching, the apparatus provides a photographic record of both the energy distribution function and a Langmuir probe characteristic. (The latter is not shown in the accompanying photographs.) At the end of a recording a modulation frequency voltage of known amplitude is applied to the amplifying equipment to enable a scale to be fitted to the energy distribution curve. The energy axis is calibrated by suppressing the oscillograph spot at convenient voltage intervals.

The accompanying figures give some preliminary results obtained in a hot cathode discharge in hydrogen at 0.055 mm. mercury pressure and a tube current of 200 mA. In Fig. 1, the probe is located in the brightest part of the striation. Attention is directed to the presence of a group of electrons having energies considerably greater than the mean. In Fig. 2 the probe is in the middle of the dark space between striations. (In the figures the short horizontal line represents a concentration of 10^6 electrons/c.c./voltage energy range, and the oscillograph spot has been suppressed at 2-volt intervals.)

It is appreciated that the anisotropy of the velocity distribution, particularly in the regions of high field, reduces the precision of the results. An energy spectrometer employing a collimated sample beam and analysis by retardation is under construction. It is hoped to publish further details, both of the experimental methods and of results and conclusions, at a later date.

Infra-red Spectra of Fluorinated Hydrocarbons

WE have recently examined for analytical purposes the infra-red spectra of some fully fluorinated hydrocarbons. Complex interactions occur in compounds of this type, and it is not to be expected that the absorption frequencies of any particular structural group will be constant: but nevertheless some regularities have been observed which may be useful.

Perfluoro compound	800-850 cm ⁻¹	860-840 cm ⁻¹
1 Decalin	—	860, 845
2 2:7 Dimethyl decalin	745*	853
3 2:9 Dimethyl decalin	738*	850
4 1:6 Dimethyl decalin	744*	848
5 2:6 Dimethyl decalin	738*	850
6 1:3 Dimethyl cyclohexane	733*	859
7 1:6 Dicyclohexyl hexane	632	849
8 1:5 Dicyclohexyl pentane	639	848
9 1:4 Dicyclohexyl butane	676	848
10 1:2 Dicyclohexyl ethane	709	848
11 Dicyclohexyl methane	720	845
12 Dicyclohexyl	738	852

* Denotes compound with CF—CF₂ group

The spectra of simple fluorine-containing compounds have been studied by several workers, and more complex molecules have been examined by Thompson and Temple¹ and by many others²⁻⁷. Some spectra are also included in the American Petroleum Institute (A.P.I.) series. However, in none of the latter cases are any vibrational assignments available.

The compounds examined are listed in the table. They were used as liquid capillary films or as solid mulls in paraffin, and the spectra were obtained with a Perkin-Elmer 21B double-beam automatic recording spectrophotometer with a rock-salt prism.

The most striking feature of the spectra examined is the contrast between the number and intensities of absorption bands in the range 800-850 cm⁻¹ in materials containing the CF₂ group and those in which this group is absent. Compounds containing the CF₂ group show a considerable number of strong absorptions in this region, whereas the unsubstituted cyclic compounds and the open-chain compounds with cyclic end-groups show, at most, a single band. This is true also of the great majority of the published spectra of fluorocarbons. Perfluorocyclopentane, for example, does not absorb in the range 800-850 cm⁻¹, and we find only a weak band at 730 cm⁻¹ in perfluorocyclohexane. The corresponding monochloro derivative, C₆F₁₁Cl, does not absorb in this region. Neither perfluorodecalin nor any of the compounds in the series perfluorodicyclohexyl methane to perfluorodicyclohexyl hexane shows more than a single band in the range 800-850 cm⁻¹.

Closer examination of this region reveals that a band occurs consistently in the range 745-730 cm⁻¹ in the spectra of those compounds which contain the CF—CF₂ or CF₂—CF₂ group. This suggests that some vibration of the CF₂ group, possibly the deformation mode, may be sufficiently stabilized in frequency when it is adjacent to a CF or CF₂ group to give a characteristic absorption. With this possibility in mind, we have examined the spectra of as many fluorinated compounds as we have been able to trace in the literature. Spectra of partially fluorinated aromatic compounds have been ignored, as aromatic ring vibrations can be expected to absorb in the same region; but apart from these we have found that a band in the 745-730 cm⁻¹ region appears in the spectra of 35 out of 48 compounds containing the CF—CF₂ or CF₂—CF₂ group, and that apart from perfluoroethane⁸, which may be expected to be abnormal, all the exceptions contain functional groups in the immediate vicinity of the CF—CF₂ group. Thus, the great majority contain the structure R—CO, R—C= on R—CFCl, in which interactions are only to be expected. In contrast to this, only six of fifty-six fluorinated compounds which did not contain the group showed absorption in the stated region. It appears, therefore, that the CF—CF₂ or CF₂—CF₂

group will give rise to absorption in the 745-730 cm⁻¹ region provided it is sufficiently far removed from the influence of functional groups. This is particularly well illustrated by the spectra of the compounds C₂F₅.COOCH₂CF₃⁹ and C₂H₅.COOCH₂CF₃¹⁰; C₂F₅.COOC₂H₅¹¹ and C₂H₅.COOC₂H₅¹²; and C₂F₅—S—S—C₂F₅¹³ and CF₃—S—S—CF₃¹⁴. The first compound of each of these pairs absorbs strongly at 740 cm⁻¹, whereas the second does not.

Another interesting feature of our spectra is the single absorption band in the range 800-850 cm⁻¹ shown by the series of compounds perfluorodicyclohexyl hexane to perfluorodicyclohexyl. The first member absorbs at 662 cm⁻¹ and the band moves progressively towards higher frequencies with decrease in the number of carbon atoms separating the two rings. Perfluorodecalin shows a similar band at 755 cm⁻¹ and it may be associated with a C—F deformation.

In all the compounds we have examined, and in all the spectra of fully fluorinated cyclic compounds in the A.P.I. series, a band appears in the range 860-840 cm⁻¹. This may be associated with a ring CF₂ vibration since it is usually absent from the spectra of open-chain materials; but it could also arise from the C—C vibrations of the ring.

The perfluorodecalin and the dicyclohexyl compounds also show complex patterns of intense bands in the range 1,350-1,200 cm⁻¹ arising from C—F stretching-modes; but these vary considerably with small structural changes and no regularities can be observed.

Thanks are due to Dr. N. L. J. Megson, of the Royal Aircraft Establishment, Farnborough, for supplying the samples and also to the Chief Scientist, Ministry of Supply, for permission to publish this note.

Use of Adsorption Columns in the Analysis of Soap and Detergent-stabilized Emulsions

METHODS at present available for the determination of the total materials in aqueous emulsions involve cracking the emulsion, separating the non-aqueous phase by solvent extraction or filtration, and weighing the products prior to analytical investigation. The need for a rapid means of isolating the components of such systems has led to the development of a technique employing adsorbents containing an ion-exchange resin, whereby the separation of an oil-in-water emulsion (for example, wool-scouring liquors) can be achieved. This has been suggested previously¹ as being applicable to large-scale cracking and recovery of emulsified grease from industrial effluents.

In the present work, using columns of 'ZeoKarb 225' ('Permutit') in bead form, mixed with powdered animal charcoal, percolation of soap solutions and emulsions gave clear liquors from which organic matter had been removed. The presence of charcoal diminishes the rate of percolation that occurs with resin alone and increases the extent of adsorption: it is not yet clear whether the charcoal functions purely mechanically or as an additional adsorptive material. Preparation of the columns involves regeneration of the resin and Soxhlet extraction with the solvents to be used for elution. Percolation of the emulsion and subsequent elution with a series of solvents resulted in the isolation of the separate components. With pure soaps, over the concentration-range 0.05-0.4 per cent, elution with ethanol gave a 98-100 per cent recovery of the corresponding fatty acids; with purified, substantially acid-free lanolin, stabilized by pure soaps, ethanol elution gave a 99 per cent yield of fatty acid (calculated on the soap used), and subsequent elution with trichlorethylene gave a 99 per cent yield of lanolin. These two fractions were identified with the pure materials by means of their infra-red absorption spectra, which are characteristic. The fatty acid was also determined by alkali titration.

Under these conditions, therefore, it is possible to obtain an almost theoretical yield of the separate components quite readily. In the case of sodium cetyl sulphate, the pure material was retained on the column, but proved most difficult to remove. Eventually, it was found that elution with ethylene glycol and subsequent titration with aqueous sodium hydroxide indicated a 100 per cent yield of cetyl hydrogen sulphate (identified as cetyl alcohol after hydrolysis with hydrochloric acid). Emulsions stabilized with sodium cetyl sulphate were also estimated, the lanolin being removed from the column by trichlorethylene, and the cetyl hydrogen sulphate afterwards removed and determined as above.

This method has been extended to the analysis of emulsions of a mineral oil (Shell 'Clavus 27') and of a vegetable oil (olive oil), reproducible results being obtained. A more detailed account of the work will be published elsewhere.

Molecular Structure of Fluorene

THERE has been considerable discussion during the past thirty years or so about the shape and in particular about the planarity of the fluorene molecule. If the molecule is not flat, then there is the possibility of obtaining optical isomers with unsymmetrically substituted fluorene derivatives, and some claims have been put forward that such isomers have been resolved. A qualitative estimation of the main X-ray crystal reflexions from fluorene together with optical and magnetic data led one of us some years ago¹ to the conclusion that the fluorene molecule was non-planar. The consequences in regard to optical isomerism were discussed by Cook and Iball², who gave a brief review of the literature on the subject.

Fluorene ($C_{12}H_8$)

We have now completed a detailed quantitative crystal analysis of this compound, including two-dimensional Fourier syntheses down each of the three axes of the orthorhombic unit cell. Full details of the analysis will be published elsewhere. Here we wish to give the results in regard to the size and shape of the molecule. The accompanying figure gives the bond-lengths (Å) and the bond-angles. The mean bond-length in the benzene ring is 1.403 Å, with a standard deviation of 0.007 Å. The space group is $Pn\bar{3}m$, and therefore, since there are only four molecules per unit cell, the molecule possesses a plane of symmetry which coincides with the (001) plane of the crystal. The carbon atoms all lie on a plane which can be represented in the unit cell by the equation $y = 1.4375x + 11.0947$ (unit cell dimensions are, $a = 8.49 \pm 0.01$; $b = 5.72 \pm 0.01$; $c = 18.97 \pm 0.10$ Å). The maximum deviation of the atoms from this plane is 0.030 Å; root mean square deviation is 0.017 Å. It is clear, therefore, that the molecule is planar, and unless the molecule has a different shape in solution from that which it has in the solid there can be no possibility of optical isomerism.

Bashforth-Adams Method for the Numerical Solution of Differential Equations

SEVERAL current text-books on numerical mathematics give descriptions of what is called the 'Bashforth-Adams' process for the solution of differential equations. The method is usually dismissed with a statement to the effect that, since it includes no adequate checking procedure, it is of little use.

Now, although this remark is true of the process envisaged by the authors of the texts, it is not true of the technique developed by Bashforth and Adams, which we can only suppose has been successively retranscribed from some incorrect secondary source by later writers.

To set the matter right, it was thought worth while to publish the following brief note. Page

references are to pages of the original text of Bashforth and Adams¹, and the notation is as given there, except that we have replaced the (Δu_s) of the original authors by the modern (∇u_s) .

In the first place, taking the equation as:

$$\frac{dy}{dt} = f\left(\frac{dy}{dt}, y, t\right) \quad (1)$$

it is pointed out (p. 16) that repeated differentiation of (1) will enable general values of $\frac{d^2y}{dt^2}$, $\frac{d^3y}{dt^3}$, etc., to be found in terms of y and t .

Next, assuming that $y = y_0$, $\frac{dy}{dt} = \left(\frac{dy}{dt}\right)_0$ when $t = t_0$, expansions for y_1 and $\left(\frac{dy}{dt}\right)_1$ at the end of an interval (δt_0) are given as Taylor series:

$$y_1 = y_0 + \left(\frac{dy}{dt}\right)_0 (\delta t_0) + \frac{1}{2!} \left(\frac{d^2y}{dt^2}\right)_0 (\delta t_0)^2 + \dots$$

$$\left(\frac{dy}{dt}\right)_1 = \left(\frac{dy}{dt}\right)_0 + \left(\frac{d^2y}{dt^2}\right)_0 (\delta t_0) + \frac{1}{2!} \left(\frac{d^3y}{dt^3}\right)_0 (\delta t_0)^2 + \dots$$

These are to be used to find initial values of y_n , $\left(\frac{dy}{dt}\right)_n$ ($n = 1, 2$, etc.), to start subsequent interpolatory processes, and some observations on the use and convergence of such Taylor series follow.

From this point the authors address themselves to the solution of the type of equation of principal interest in their own work:

$$\frac{dy}{dt} = f(y, t) \quad (=f, \text{ say}). \quad (2)$$

The backward difference interpolation formula:

$$f_n = f_0 + \frac{n}{1!} \nabla f_0 + \frac{n(n+1)}{2!} \nabla^2 f_0 + \dots$$

is integrated (p. 18) to give:

$$y_0 - y_{-1} = \int_{-1}^0 f_n dn,$$

or

$$y_1 - y_{-1} + (\delta t) \left[f_0 - \frac{1}{2} \nabla f_0 - \frac{1}{12} \nabla^2 f_0 - \frac{1}{24} \nabla^3 f_0 - \frac{19}{720} \nabla^4 f_0 - \frac{3}{160} \nabla^5 f_0 - \dots \right] \quad (3)$$

and

$$y_1 - y_0 = \int_0^1 f_n dn,$$

or

$$y_1 = y_0 + (\delta t) \left[f_0 + \frac{1}{2} \nabla f_0 + \frac{5}{12} \nabla^2 f_0 + \frac{3}{8} \nabla^3 f_0 + \frac{251}{720} \nabla^4 f_0 + \frac{95}{288} \nabla^5 f_0 + \dots \right] \quad (4)$$

It is the second of these formulae which is usually given as the basis of the Bashforth-Adams method, whereas, in fact (p. 19), the authors suggest that (4) be used to predict a value for y_1 and that this value is to be checked and, if necessary, corrected by means of (3), which they rightly point out is of much greater accuracy than (4) for the same number of terms.

The analysis concludes with some formulae for the cyclic refinement of a predicted value when the difference between this and the more accurate version obtained by means of (3) is small enough for squares to be neglected (pp. 19-20).

Tables are also provided (pp. 58-62) to facilitate the calculation of the quantities $\frac{19}{720} \nabla^4$, $\frac{3}{160} \nabla^5$, etc., occurring in (3), and give additional proof that the correction formula was intended for serious use.

It will be clear to the reader that the full method, as described above, is an eminently practical one, and that it differs only very slightly (in the detailed formulae) from the prediction-correction process usually known as Milne's method, which is much favoured at the present time.

Osmotic Pressure of Bull Semen Diluents

BULL semen is usually diluted with egg yolk phosphate¹ or egg yolk citrate buffer² before being used for artificial insemination. The former consists of equal volumes of freshly separated egg yolk and phosphate buffer, pH 7.4 (2 gm. Na₂HPO₄·12H₂O, 0.2 gm. KH₂PO₄ and water to 100 ml.); the latter consists of equal volumes of egg yolk and sodium citrate (2.9-3.9 gm. Na₃C₆H₅O₇·2H₂O and water to 100 ml.; pH adjusted to 6.8 by addition of citric acid, 2.8-10 per cent). Various combinations of bacteriostatic and/or bacteriocidal substances are often added to these semen diluents. The freezing point depressions (Δ) of these diluents, of certain others, and of bull seminal plasma were measured by Ramsay's micro-method³, and the results are given in Table 1. The value given for bull seminal plasma is the mean of forty determinations, using ten bulls of different breeds (Ayrshire, Dexter, Red Poll, Shorthorn and Friesian) over a period of one month. The standard error of $\bar{\Delta}$ (-0.53) is 0.005. Dr. R. Aschaffenburg, of the National Institute for Research in Dairying, Shinfield, has obtained very similar values to those quoted above, using the Hill-Baldeo vapour-pressure technique (personal communication).

Table 1. FREEZING POINT DEPRESSIONS (DEG. C.)

Bull seminal plasma	-0.53
Phosphate buffer + egg yolk (equal vol.)	-0.45
Citrate buffer, 3.92 per cent* + egg yolk (equal vol.)	-0.63
Citrate buffer, 3.4 per cent + egg yolk (equal vol.), containing 0.15 per cent sulphamamide and 250 I.U. streptomycin calcium chloride/ml.	-0.64
Sperm Ringer (Mann, 1946)	-0.53
SGO-2 (Milovanov, 1938)	-0.59
0.9 per cent sodium chloride	-0.54

* w/v here and elsewhere.

The most recent other experiments on this subject are those of Salisbury *et al.*⁴. They found that $\bar{\Delta}$ of bull semen, as distinct from seminal plasma, was -0.587. We found it impossible to measure the freezing point depression of bull semen accurately, using Ramsay's method, because of the opacity of the semen. Apart from this, the freezing point depression of seminal plasma is more meaningful than the freezing point depression of semen, which, in the case of the experiments of Salisbury *et al.*, consisted of seminal plasma containing an unspecified number of dead spermatozoa, the effect of which on such measurements is unknown.

Not much evidence is available on the tolerance of bull spermatozoa to media with different osmotic pressures; but it would seem desirable to use a diluent with about the same osmotic pressure as seminal plasma. In the case of egg yolk citrate buffer containing 0.15 per cent sulphanilamide, this can be achieved by using equal volumes of egg yolk and a 2.875 per cent solution of sodium citrate ($2H_2O$), made up in water containing 0.3 per cent sulphanilamide, brought to pH 6.8 with 5.6 per cent citric acid, also made up in water containing 0.3 per cent sulphanilamide. In the case of egg yolk phosphate buffer containing 0.15 per cent sulphanilamide, a mixture containing equal volumes of egg yolk and phosphate buffer (2 gm. $Na_2HPO_4 \cdot 12H_2O$, 0.2 gm. KH_2PO_4 + 75 ml. water containing 0.3 per cent sulphanilamide) is isotonic with bull seminal plasma. The concentrations in which penicillin and streptomycin are normally added are such as to have only a small effect on the osmotic pressure of the diluent. The freezing point depression of egg yolk itself is -0.58 to -0.60° .

This work is supported by the Medical Research Council; further details will be published in due course.

Semen Diluents in the Artificial Insemination of Cattle

A NUMBER of studies have been made of the effects of different diluents, with and without the addition of bactericidal or bacteriostatic substances, on the fertilizing capacity of bull semen. Experiments in the United States, where most of the investigations have been made, have been reviewed by Easterbrooks¹, while Rottensten and Oestergaard² have described a series of experiments in Denmark; but no systematic examination of this problem has been made in the United Kingdom, and the American experiments have been on a comparatively small scale, which obviated the possibility of a comprehensive investigation. A large experiment in Britain, involving four Milk Marketing Board artificial insemination centres and their sub-centres, was therefore started in February 1951. The experiment was designed to find out which of the two diluents commonly used in artificial insemination, egg-yolk citrate buffer (equal volumes of 3.2 per cent sodium citrate, pH adjusted to 6.8 with citric acid, and egg-yolk) and egg-yolk phosphate buffer (equal volumes of phosphate buffer, pH 7.4 (2 per cent $Na_2HPO_4 \cdot 12H_2O$ and 0.2 per cent KH_2PO_4 , and egg-yolk), was the better in the sense of being associated with the higher conception-rate, the buffers being used with and without all possible combinations of

sulphanilamide (1.5 mgm./ml.), penicillin (500 units/ml.) and streptomycin (500 µgm./ml.).

The experiment involved the insemination of 68,713 cows with semen from 134 bulls; the split-sample technique was used throughout. A considerable fraction of the computations involved in the analysis of the results was done on EDSAC I, and we are much indebted to Dr. M. V. Wilkes, director of the Mathematical Laboratory, Cambridge, for allowing the electronic calculator to be used for this purpose.

The results show that: (1) egg-yolk phosphate buffer + penicillin improved the conception-rate, as compared with egg-yolk citrate buffer alone, by 9.3 per cent; (2) egg-yolk citrate buffer + sulphanilamide, penicillin and streptomycin improved the conception-rate, as compared with egg-yolk citrate buffer alone, by 6.8 per cent; and (3) egg-yolk phosphate buffer alone was 5.5 per cent better than egg-yolk citrate buffer alone.

The difference between the improvements cited in (1) and (2) is insufficient to justify the adoption of egg-yolk phosphate buffer + penicillin at artificial insemination centres, particularly as egg-yolk citrate buffer has certain advantages, from the point of view of the visibility of the spermatozoa in it, over egg-yolk phosphate buffer. The increase in conception-rate using egg-yolk citrate buffer + sulphanilamide, penicillin and streptomycin is, however, of considerable economic importance.

The details of this work will be published elsewhere.

We are indebted to Sir Ronald A. Fisher for his guidance in the statistical analyses; and also to the members of the Milk Marketing Board's veterinary and technical staffs for their invaluable co-operation in these experiments.

Artificial Production of Incomplete Influenza Virus

DIFFERENT strains of influenza virus yield different proportions of incomplete particles on heavy infection of the allantois¹; and members of the influenza group can be arranged in a gradient based on this property². The phenomenon itself remains unexplained, as is, indeed, the mechanism of incomplete virus production. In an approach to this problem we searched for other characteristics which would vary in gradient fashion, and hoped to establish a correlation between some better-known viral functions and the change in infectivity.

We have examined the rate of adsorption and elution in the allantois, the 'minimum receptor requirements', the extent to which the strains can inactivate the receptor substance, and the speed with which they are taken up by cells. All these properties showed uneven distribution among the strains, as

will be published in detail elsewhere. However, to date only the rate of viropexis appeared to give the same gradient as that of incomplete virus production, the strain taken up fastest (*LEE*) producing the smallest proportion of incomplete particles. On the strength of this observation the following working hypothesis was formed.

In the period between adsorption to infectible cells and viropexis the particles 'browse' over the surface of the cells², that is, during their two-dimensional thermal movement the viral enzyme groupings will come into contact with specific substrate groups, act on them, and thus reduce the average concentration of substrate over the whole cellular surface. Obviously, the decrease in substrate concentration will be proportionate to the relative number of enzyme units, and to the average time the virus spends outside the cell. It is assumed that a certain amount of intact receptor substance is required for complete virus production, and that below a critical substrate density the cell will produce non-infective particles. The fact that incomplete virus is produced (a) only in the first cycle, (b) only after heavy infective inocula, and (c) to different extents in different strains, is explained by (a) the first cycle being considerably longer than any subsequent cycles³, due mainly to slower viropexis⁴; (b) that effective reduction of overall substrate density can be achieved only by large numbers of virus particles acting for a long time; and (c) that different strains spend different periods on the outer surface of the membrane prior to being taken up. It follows from the foregoing that a treatment which renders the substrate non-attackable or which reduces the lag between adsorption and uptake should prevent the production of incomplete virus; similarly, artificial destruction of the substrate—provided it does not also prevent infection—should result in the production of incomplete particles even in those strains where this would not normally occur, and even after dilute inocula where it is not known to occur with any strain.

The crucial experiment was built around the 'receptor modifying' effect of the metaperiodate-ion⁵. It is known that influenza virus enzymes cannot act on cellular receptors which have been oxidized by appropriate amounts of IO_4^- ; however, such cells are still infectible by the virus. Thus, eggs were given allantoic inocula of 1.0 ml. 0.01 *M* potassium periodate, and an hour later 0.25 ml. 0.1 *M* glycerol to neutralize excess periodate. Following this, 10^4 or 10^6 *ID*₅₀ of fresh *PR8* (*A*) or *LEE* (*B*) virus were inoculated. The fluids, harvested at the height of infectivity (that is, sixteen hours after the concentrated and forty-two hours after the dilute seed), were titrated for infectivity and haemagglutinin content. The results are shown in the accompanying table.

PRODUCTION OF INCOMPLETE VIRUS IN IO_4^- TREATED EGGS

Treatment	Inoculum		Replicates	Yield		
	Strain	Dose		<i>ID</i> /ml.	<i>HA</i> /ml.	<i>ID</i> / <i>HA</i> ± s.d. error
Nil	<i>PR8</i>	10^6	15	7.61	3.35	4.26 ± 0.18*
		10^4	18	9.22	3.31	6.01 ± 0.16
	<i>LEE</i>	10^6	25	9.24	3.12	6.11 ± 0.09
		10^4	17	9.08	2.65	6.17 ± 0.09
KIO_4	<i>PR8</i>	10^6	18	6.43	2.54	3.95 ± 0.10*
		10^4	15	7.73	2.99	4.75 ± 0.12*
	<i>LEE</i>	10^6	16	7.83	3.06	4.78 ± 0.13*
		10^4	17	7.61	3.29	4.31 ± 0.14*

Geometric mean infectivity (*ID*) and haemagglutinin (*HA*) titres are expressed in log₁₀ units.
Significant production of incomplete virus is marked with an asterisk.

The normal ratio of infectivity to haemagglutinin (*ID*/*HA* ratio) is 10^{4-10} . In the absence of pre-treatment with IO_4^- both strains attain this ratio after dilute inocula, and *LEE* even after the concentrated one; thus only large doses of *PR8* lead to the production of 'incomplete' virus particles, with a resultant drop in the *ID*/*HA* ratio. After IO_4^- treatment, on the other hand, all combinations of strains and inocula show ratios significantly lower than the normal, more than 90 per cent of the particles yielded being incomplete. Control experiments have satisfied us that the target of IO_4^- action was the host cell and not the infecting virus.

These results amount to the realization of the second set of predictions, and thus to a positive proof of our hypothesis. The rest of the predictions, which should constitute the indirect proof, are either not amenable to experimental testing—there are at present no means known to render the intact substrate non-attackable—or are well-established empirical facts, namely, the absence of incomplete virus production in later cycles.

Influence of Nitrate Ion upon the Synergistic Effects of Glucose and *k*-Strophanthoside

In the present report, we offer evidence to show that glucose is one of the factors limiting the positive inotropic response of the driven ventricle to *k*-strophanthoside (*Strophosid*-Sandoz), and that the magnitude of the reaction to glucose is greater when nitrate rather than chloride is the chief anionic constituent of the nutrient medium.

Electrically driven strips of rats' ventricles were employed as the test objects in the present study. Since the methods of preparing the muscle sections and other details of experimental technique have already been described in previous reports from this laboratory¹⁻³, details of methodology will be omitted from the present communication. All experiments were made in the presence of continuously flowing media that were replenished at the rate of 500 ml./hr. and gassed by a vigorous flow of oxygen through the muscle chamber. The pH of the solutions at 37° C. was 8.3.

The strips were first standardized on 'reference' solution (see table) and then subjected to a low (3.2 mM) calcium glucose-free solution in order to accelerate the 'tiring' process.

COMPOSITION OF STANDARD REFERENCE SOLUTIONS (MILLIMOLES PER LITER)

	Na	K	Ca	Glucose
NO_3^- or Cl^- HCO_3^-	154 7.15	5.63	5.50	5.50

Effect of glucose and *l*-strophanthoside on hypodynamic ventricles. Activity values shown above are expressed relative to the amplitude developed during pre-experimental equilibration on standard reference solution. Negative time identifies the post-standardization fatigue period; S, the addition of *l*-strophanthoside (final concentration 5.73×10^{-4} mM); and G, the administration of glucose (final concentration 5.50 mM). The plotted points in each experimental category are mean values obtained on five ventricle strips and the vertical lines are their respective standard errors.

When the activity of driven ventricle strips that were maintained on the latter solutions had declined to about 50 per cent of the equilibration value, the addition of glucose produced an increase in the contractile response which could be potentiated by the subsequent addition of *l*-strophanthoside. There was no enhancement of the contraction amplitude if *l*-strophanthoside were added in the absence of glucose. The accompanying figure illustrates that the addition of the drug to the medium in a quantity sufficient to yield a 5.73×10^{-4} molar concentration of *l*-strophanthoside (calculated on the assumption that the molecular weight is 872⁴) has no effect until subsequent treatment with glucose.

The influence of inorganic anions upon the response of the substrate-depleted muscle to glucose can be assessed by comparing the two dashed curves in the figure. Within the time restrictions of the test, the response of the fatigued muscles to the addition of glucose was greater in nitrate- than in chloride-Ringer's. Although the subsequent administration of *l*-strophanthoside produced an enhancement of contraction amplitude, the increase was of a lesser magnitude in the case of chloride than of the nitrate series.

Our findings concerning the potentiating effect of nitrates upon the inotropic response to glucose are in general accord with the observations of Sandow⁵, who found that the twitch-tension of the frog's gastrocnemius was augmented in the presence of this anion. Although it is likely that an increase in membrane permeability is concerned in the overall mechanism, its precise role is obscure. On the basis of the present results with glucose it is tempting to ascribe the mechanical enhancement observed in the presence of nitrate ion to the increased flux of sugar into the cell, but the fact cannot be discounted that other substances (for example, K^+) which are known to accompany the inward diffusion of glucose might be more immediately related to the observed effect.

By reference to the figure it can be seen that prior treatment with *l*-strophanthoside decreased the response to glucose of ventricles maintained in nitrate-Ringer's. Owing to the fact that the glycogen content of the muscles surviving in the absence of substrate was low^{6,7}, it can be presumed that the oxidative synthesis of $\sim$ ph was severely reduced; hence any manoeuvre (such as the addition of *l*-strophanthoside or a similar agent⁸) that tends to increase contractile activity by accelerating $\sim$ ph breakdown would be limited in its effectiveness by the amount of oxidizable substrate present. The failure of substrate-depleted ventricles to respond fully to glucose after a 25-min. period of pretreatment with *l*-strophanthoside may be interpreted on the basis that the substrate was entering a muscle which was partially depleted of high-energy phosphate bonds.

We are indebted to Mr. Mungai N'Joroge for help in the preliminary phases of this work, and to Mr. Harry Althouse, of the Sandoz Corporation, for generous supplies of *l*-strophanthoside. These studies were supported, in part, by a grant from the Stanford Medical Research Fund and by a contract between the Office of Naval Research and Stanford University, ONR-N6-26137.

Progesterone Secretion in Ewes

PROGESTERONE secretion during the oestrous cycle of ewes has been measured by means of a chemical assay, with a limit of sensitivity of 0.1 μ gm. per ml. of blood¹. The breeding behaviour of Romney ewes was followed by means of raddled teasers. In fifty-one of these ewes, assays were carried out on blood samples obtained by laparotomy from the ovarian vein draining the active ovary. The results were analysed for an average oestrous cycle of seventeen days, commencing from the day of onset of oestrus.

For the first two days, the amount present was less than 0.1 μ gm. per ml. blood. Detectable amounts were present from the third or fourth day, and increased to about the ninth day. The average quantity remained relatively high until the sixteenth day, with a sudden fall on the seventeenth day. In no case was progesterone detected in blood obtained from the jugular vein at the same time.

There was considerable variation between sheep on the same day of the oestrous cycle. For example, on the eleventh day, the average concentration for six ewes was 1.7, and the range was 0.5–3.4 μ gm. per ml. blood. The quantity of progesterone in the blood of yearling ewes fell within the range of that of three-year old sheep.

Variations as great as those recorded for different sheep may perhaps occur throughout one day in the individual ewe. The absolute amount of progesterone present at any moment may be less important than the daily total, or even than a minimal quantity. A further variable is probably the responsiveness of the target organs. The balance between progesterone and the oestrogens may be the vital factor.

This work is to be continued, and will be more fully reported elsewhere.

Participation of the Oxidative Pathway in Yeast Respiration

RECENT work has demonstrated the widespread occurrence of enzymes which *in vitro* catalyse reactions in the breakdown of glucose by the so-called hexose monophosphate shunt or oxidative pathway (as distinct from the classical glycolytic route or Embden-Meyerhof-Parnas sequence). Thus the recognition of sedoheptulose phosphate as a labile intermediate and its participation in a cyclic sequence of reactions by which glucose might be completely oxidized¹ has extended the earlier work of Dickens and others and given grounds for supposing that a non-glycolytic breakdown of glucose may occur normally in certain living cells and may, in fact, be a major route of glucose catabolism. The present communication describes results from resting yeast suspensions which are in accord with this supposition.

The method which was used has already been successfully employed by Bloom, Stetten and Stetten to confirm their earlier results from animal tissues which indicated that, in liver slices particularly, the oxidative pathway plays an important part². It is based on the consideration that the mechanism of glucose breakdown will determine the relative rates of release of its constituent carbon atoms into the respired carbon dioxide. Specifically, the carbon dioxide released if the oxidative pathway was operating would be expected to be initially richer in carbon-1 than carbon-6, whereas, if the Embden-Meyerhof-Parnas sequence was the only method of glucose breakdown, carbons-1 and 6 would be expected to appear at equal rates in the respired carbon dioxide.

The yeast (*Saccharomyces cerevisiae*) was grown at 25° C. on a glucose and mineral salts medium. Aliquots of a thin suspension of washed cells in phosphate buffer at pH 5.0, on being transferred to Warburg flasks and shaken at 25° C., showed a negligible endogenous oxygen uptake. When glucose was added, oxygen uptake (with respiratory quotient 1.0-1.2) continued until about 40 per cent of it had

been oxidized; but most of the experiments were terminated when 10-20 per cent of the supplied glucose had been respired. The experimental period was begun by tipping from the side-arms of duplicate flasks either 10 μ M glucose-1-¹⁴C or 10 μ M glucose-6-¹⁴C; the rates of respiration on the two substrates were the same. The carbon dioxide absorbed by potassium hydroxide in the centre well was converted with carbon dioxide carrier into barium carbonate the radioactivity of which was determined with a gas-flow proportional counter^{3,4}. The specific activity of the respired carbon dioxide was determined and the yield of carbon-14 dioxide (in μ mo.) from each of the glucose samples was evaluated. This was then expressed as a percentage of the supplied activity to arrive at the ratio

$$\frac{\% \text{ radiochemical yield from 1-}^{14}\text{C glucose}}{\% \text{ radiochemical yield from 6-}^{14}\text{C glucose}}$$

This ratio has been designated in the tables as ' C_1/C_6 '.

Table 1 shows results from two different yeast samples. It is clear that, whereas the contribution of the C-1 carbon of the glucose to the respired carbon dioxide was relatively large, and its specific activity greater than that of the supplied glucose, that of the C-6 carbon was small. It further appears that, depending on the cultural conditions, the ratio may assume different values. The point we wish to emphasize here, however, is that in none of our experiments have values for the ' C_1/C_6 ' ratio in the early stages of glucose breakdown been close to unity; values ranging from 2.0 to 5.7 have been recorded, and these must be regarded as minimal since earlier sampling, had it been practicable, would have provided even higher values. These results are taken to indicate that the oxidative pathway was playing a considerable part in the respiration of the cells.

In another type of experiment, carbon dioxide samples were collected at intervals from each of two aliquots of yeast, one respiring on glucose-1-¹⁴C and the other on glucose-6-¹⁴C. The results are shown in Table 2. During the first period it will be seen that the contribution of C-1 to the carbon dioxide was 2.5 times that of C-6, but that in the later intervals C-6 appeared in increasing amount while the yield of C-1 was declining, so that the ratio fell to 0.38. At the termination of the experiment, when oxygen uptake had virtually ceased, the total per cent yields from C-1 and C-6 were similar, giving an overall ratio of 1.04 and indicating that no permanent assimilation of C-6 over C-1 had occurred. The changing ratio is in accordance with the suggestion that, at least for some of the glucose molecules respired, carbon-1 is split off at an early stage, as would be expected if they were taking the oxidative pathway, and the fact that C-6 appears in larger quantities later would indicate that the reactions leading to its conversion to carbon dioxide succeed those for C-1 release.

TABLE 1. RECOVERY OF CARBON-14 IN THE RESPIRED CARBON DIOXIDE FROM YEAST CELLS SUPPLIED WITH C-1 OR C-6 LABELLED GLUCOSE

Yeast	Glucose added	Specific activity of glucose (m μ o./mgm.O)	m μ o. added	Specific activity of CO ₂ (m μ o./mgm.O)	m μ o. recovered	Recovered (per cent)	' C_1/C_6 '
12-hr. cells 'aerated' during growth	10 μ M 1- ¹⁴ C	5.40	4.03	5.92	1.24	31.0	2.0
	10 μ M 6- ¹⁴ C	4.71	3.40	2.50	0.52	15.5	
18-hr. cells 'not aerated'	10 μ M 1- ¹⁴ C	18.10	18.40	27.10	2.90	23.5	5.2
	10 μ M 6- ¹⁴ C	4.71	3.40	1.42	0.15	4.8	

Table 2. VARIATIONS IN THE RATIO O_2/O_2^* DURING SUCCESSIVE TIME INTERVALS

	Period I (3 hr.)	Period II (3 hr.)	Period III (5 hr.)	Total
Per cent radiochemical yield from glucose-1- ^{14}C	17.2	13.9	2.2	33.3
Per cent radiochemical yield from glucose-6- ^{14}C	6.8	19.4	5.9	32.1
O_2/O_2^*	2.53	0.72	0.38	1.04

The above methods have been successfully applied in experiments with various higher plant tissues, and here also the results give some basis for discounting the Embden-Meyerhof-Parnas pathway as the sole mechanism of glucose breakdown. A complete report of this work will be published elsewhere.

This research was carried out at the Brookhaven National Laboratory under the auspices of the United States Atomic Energy Commission. We are indebted to Dr. F. G. Sherman, of Brown University, for the yeast culture, and to Dr. B. L. Horecker, of the National Institutes of Health, for stimulating and helpful discussions.

Dependence of X-ray Sensitivity of Bacteriophage on Phase State and Temperature

SEVERAL studies have shown that biological materials are more resistant to ionizing radiations at extremely low temperatures¹⁻⁴. This is usually explained by assuming that diffusion processes involving 'poisons' produced by radiations (OH, HO_2 , H_2O_2 , etc.) are greatly retarded at low temperatures where there would be negligible free water. The above investigations have not been closely concerned with the region around 0° C. where the liquid-solid phase change would be of importance. The purpose of this report is to describe the influence of temperature (-16° to 37°) and phase state (liquid or solid) on the radiosensitivity of a bacterial virus.

The test organism was T2 bacteriophage, specific for *E. coli*, strain B. Suspensions of 10^4 phage/ml. in buffer (3.5 gm. Na_2HPO_4 , 1.5 gm. KH_2PO_4 , 0.1 gm. $MgSO_4$, 1,000 ml. water) were irradiated in thin glass vials kept in a constant-temperature bath and were diluted afterwards for plating; control and irradiated phage were assayed by standard methods⁵. 250-kV. X-rays at an exposure-rate of 425 r./min. were used for all irradiations. Surviving fractions were computed from controls subjected to the same temperature treatment as irradiated samples. Suspensions kept in the frozen state at the lowest temperatures (-16° and -10°) showed about 50 per cent viability to temperature treatment alone; all other tem-

peratures were not harmful as measured by titre. Phage suspensions as described above normally freeze at -0.5° C.; however, it is possible to supercool these to as low as -10° C. without great difficulty. Thus it is possible to compare radiosensitivities of test organisms that are suspended at the same temperature during irradiation in a liquid medium (supercooled) and in a solid medium (frozen).

T2 irradiated in liquid buffer displayed survival curves similar to those described by Watson⁶, the general shape (concave downward) being fairly independent of the temperature during irradiation. At higher temperatures (above 20°) the radiosensitivity is somewhat increased as previously reported by Alper⁷ for S13 bacteriophage. However, phages irradiated in frozen buffer were much more resistant to X-irradiation and the survival curves themselves were exponential. The radiosensitivity (negative logarithm of the surviving fraction of phage after sixty minutes irradiation) as a function of temperature and phase state is shown in the accompanying figure.

Different phage samples irradiated at -10° in (1) solid buffer, (2) liquid broth (5 per cent Difco nutrient broth), and (3) frozen broth, were all equally resistant to X-rays. It has been suggested that the decreased radiosensitivity in liquid broth is due to the elimination of indirect effects by certain 'protective chemicals' of the broth. Since the magnitudes of the protection afforded by liquid broth, solid buffer, and solid broth are the same, it is probable that all three methods eliminate indirect effects. Broth presumably acts by competing for radiation poisons; the solid phase probably protects by hindering the diffusion of these poisons through the supporting medium to the phage particles. It is interesting to note that Bonét-Maury has observed a discontinuity in the amount of hydrogen peroxide production by X-rays at the phase change point, approximately twice as much hydrogen peroxide being produced in the liquid phase as in the solid phase⁸. This, however, is not to be interpreted as meaning that hydrogen peroxide is necessarily the effective poison in the present study.

The residual radiosensitivity observed even when various protective agents are used is probably due to direct inactivation^{9,10}. Adams and Pollard⁹ found no significant difference between radiosensitivity for T1 bacteriophage in broth and in the dried state. They consider that all inactivation in the dried state

is due to direct effects and hence conclude that indirect effects in broth are relatively small.

This phase state phenomenon with supercooled suspensions offers a new parameter that is being used in connexion with other modifying agents to study the mechanism of cell damage by radiations.

This investigation was aided by grants from the U.S. Atomic Energy Commission and from the Dr. Wallace C. and Clara A. Abbott Memorial Fund of the University of Chicago, and was carried out in the laboratory of Prof. R. E. Zirkle.

A Technique for combining the Staining of Fixed Nuclear Material with the Subsequent Separation of Plant Tissue Into Individual Cells

FOLLOWING an earlier investigation¹, a further study has been made of the mode of action of isopropyl-phenylcarbamate. In order that the observed inhibitory effects on the elongation of *Zea mays* roots could be interpreted in terms of cell division and cell extension, it was necessary to evolve a technique which coupled staining of the nuclear material with the separation of root tips into the individual component cells. The method, developed by Brown² for *Pisum sativum*, of gently bombarding carmine-stained root tips with glass beads, failed with maize roots to give adequate cell separation unless the period of bombardment was greatly prolonged, and then too many of the cells were damaged; also the differential staining of the nucleus and cytoplasm was not good enough to allow of the detection of the earliest stages of prophase. The alternative of using a pectinase³ was then investigated, and eventually the following procedure for the separation of previously stained tissue was found to give excellent results if 'Pectinase' (Nutritional Biochemicals Company, Ohio) was employed.

The roots were first fixed in a mixture of 3 parts absolute alcohol and 1 part glacial acetic acid and stained by the Feulgen technique⁴. After washing in distilled water, the excised root tips were placed in a small volume (for example, 0.5 ml. for ten root tips 1 mm. long) of 2 per cent 'Pectinase' made up in distilled water, adjusted to pH 6.6 and saturated with toluol to minimize contamination by micro-organisms. The segments were left in the dark in the 'Pectinase' solution for 12 hr., and at the end of this period most of the 'Pectinase' was removed by a pipette and replaced by an equal volume of 3 per cent solution of a commercial pectin product ('Certo'). By repeated sucking and blowing the tips through a pipette with a fine orifice, the required state of division could be achieved; in order to prevent

a loss of cells due to their sticking to the inside of the pipette a very slow intake was followed by vigorous ejection. When a drop of such a suspension was examined under high magnification ($\times 1,500$), it was found that the cells were either completely separated or grouped into small masses of 2, 4, 8, 16 or, very rarely, 32 cells. There was no sign of damage to the individual cells, and all mitotic stages including early prophase were easily recognizable.

Since 'Pectinase' has also been found effective for the separation of fixed cells in both mature root tissue of maize and the meristems of *Vicia faba*, it is likely that this technique of combined staining and cell separation will be generally applicable.

Histological Demonstration of Alkaline Phosphatase and Non-specific Esterase by Azo-dye Methods

HISTOCHEMICAL methods^{1,2} already described are capable of greater sensitivity with reduced artefact formation when employed in a manner similar to that recently reported for the demonstration of acid phosphatase³. Increased sensitivity results from enhanced enzyme activity at an incubation temperature of 37° C., demonstration of weak foci of activity in tissues being greatly facilitated. Artefacts resulting from diffusion of enzymically liberated alpha-naphthol is avoided by increasing the speed of azo-coupling and by restriction where necessary of the rate of substrate hydrolysis. Hydrolysis is retarded preferably by reduction of the substrate concentration; this has the advantage over refrigeration of the incubation medium that fast azo-coupling is not prejudiced. For both the usual substrates, sodium alpha-naphthyl phosphate and alpha-naphthyl acetate, the most useful concentrations are 0.01–0.1 mgm./ml.

Accelerated azo-coupling results from incubation at 37° C. and from a high concentration of diazonium salt. Tetrazotized dianisidine (fast blue B), one of the most satisfactory compounds available, is best used at a concentration of 0.2–0.4 mgm./ml.; the high incubation temperature does not greatly increase its rate of breakdown or the concomitant tissue background staining. For tissues showing low residual enzyme activity the concentration of diazonium salt should be reduced to avoid excessive enzyme inhibition; otherwise, in the interests of fast azo-coupling the highest tolerated concentration is desirable.

Evidence of accelerated azo-coupling due to the catalytic effect of the quinoline derivative 'Percain' (2-butoxy-N-(2-diethylaminoethyl) cinchoninamide hydrochloride) is afforded by absence of the off-black shades of dye previously shown to be formed at a slow rate of coupling⁴. A further effect of 'Percain', present in the substrate medium at up to 0.4 per cent concentration, is considerably minimized tissue

background staining, apparently due to slowing of the rate of decomposition of the diazonium compound. The low solubility of 'Perocain' in alkaline media limits its usefulness in the method for alkaline phosphatase unless a low non-optimal pH can be employed; in the method for non-specific esterase (pH 7.5) its effects are particularly marked and in neither instance does it inhibit enzymic activity unduly.

This report is based on studies made while in receipt of a grant from the Auckland, N.Z., Division of the British Empire Cancer Campaign Society.

Spiral Development of Mycelium In *Aspergillus niger* Colonies

DURING a recent study of a large number of strains of *Aspergillus niger* we observed a morphological feature not hitherto recorded, so far as we know, for the *A. niger* group. The mycelium growing from a point-inoculation of one strain on a modified Czapek solution agar (normal Czapek solution salts, but 30 per cent sucrose instead of 3 per cent) showed a left-handed twist, or spiral development, when viewed from above in the ordinary way. The word 'spiral' is used loosely, for a form which indeed suggests the picture of a spiral nebula. The tracks both of the primary hyphae and of their lateral branches curved in a counter-clockwise sense as they advanced.

This led us to examine more closely the early development of many other strains, in order to discover whether spiral development is a general feature of *A. niger* and whether right-handed or clockwise spirals also occur. Only a very few cases of pronounced left-handed spirals were found. One such is shown in Fig. 1; the strain is *A. niger* 289, isolated from sunflower seeds; it has an orange-coloured reverse and is a poor citric acid producer. In a few strains the left-handed tendency was just detectable, but the great majority showed no spiral habit at all. One instance of well-marked right-handed spiral development was found. The mould concerned

Fig. 1. Left-handed spiral development of colony of *A. niger* 289, 2 days old at 25° C.

Fig. 2. Young mycelium of *A. japonicus* growing as counter-clockwise spiral on 'Cellophane' overlying agar medium (left), but becoming clockwise after reaching the uncovered medium (right).

proved to be a strain of *A. japonicus*, a species of the *A. niger* group characterized in part by having only one series of sterigmata.

Spiral colonies develop whether the cultures are incubated in the dark or in the light, and twist in the same sense relative to the agar surface whether the plates are kept upside-down or the right way up. In case the nature of the agar surface might be a factor determining spiral development, a disk of agar medium, separated from its dish, was inoculated on the surface which had been in contact with the glass. No change in the spiral character of the resulting colony was detected. On the other hand, *A. japonicus*, inoculated at a point near the edge of a square of 'Cellophane' lying on agar medium, showed left-handed spiral development while on the 'Cellophane', but became right-handed again after reaching the edge and spreading on to the agar (Fig. 2). The question as to how the interposition of a 'Cellophane' membrane can bring about this striking reversal remains to be explored.

Status of *Szechuanopithecus* from the Pleistocene of China

DESCRIBING a typical Pleistocene fauna (with *Ailuropoda* and *Topirus angustus*) from Koloshan, near Chungking, Szechuan, Central China, Young and Liu¹ have recently figured an isolated lower bilophodont tooth, which according to these authors should indicate a new genus of the *Ceroopithecidae*. As fossil Primates are of special interest to everybody concerned with the study of human evolution, I wish to comment on this matter.

The tooth in question is very small—7.2 mm. long and 4.0 mm. wide at its anterior part. It is regarded by the authors as a third molar "with a very much reduced talonid".

A glance at the text-figure, however, reveals that, while the specimen without doubt belongs to a *Cercopithecus*, it cannot be regarded as a last permanent molar, both on account of the general pattern and also because of the divergent roots. There is little doubt that it is a first deciduous molar (d_1) of normal type, which from the lack of comparative material—the authors mainly refer to Elliot's monograph—could not be recognized by the authors. This tooth certainly belongs to *Macacus robustus* Young, described from the same locality.

Experiments on the Cause of Dorsiventrality in Leaves

Sussex¹ has reported that in apices of potato shoots the presumptive area of I_1 , the next leaf due to arise, develops into a centric leaf, having the shape of a narrow cone, if isolated from the rest of the stem apex by a vertical cut. Such structures are what we previously called radial leaves*. He concludes that the normal dorsiventrality of the leaves is induced by the stem apex. On the other hand, in *Lupinus albus* we found that the presumptive areas of I_1 and of I_2 , the next younger leaf again, when similarly isolated, gave rise only to fully dorsiventral leaves with leaflets*. We have therefore now isolated by vertical cuts in several potato apices the presumptive area of I_1 , or of I_2 ; but these areas gave rise only to dorsiventral leaves, except in one apex which was seen to be suffering from loss of turgor some hours after the operation. In this apex the isolated I_1 area gave rise to a radial leaf. In a further series of operations on potato apices we made the isolating cuts deep and inserted thin pieces of mica, to keep them open and to prevent substances from diffusing across them. The pieces of mica were left in position for some days, by which time the isolated leaf could usually be seen to have arisen. After about a fortnight the apices were pickled and sectioned, and the cuts were found to be still open. Even in these apices all the isolated presumptive areas which developed further, eight I_1 and two I_2 areas, gave rise to dorsiventral leaves, though one of the leaves, an I_1 , was partly tubular. Many of these leaves had indeed looked conical at first when seen in the solid, but when examined in sections later they were seen to be fully dorsiventral, though their blades were often curved inwards towards the stem. These results are quite different from those reported by Sussex, and do not indicate that in potatoes the dorsiventrality of the leaves is induced by the stem apex.

However, in *Epilobium hirsutum*, which forms radial leaves very readily, we have obtained results similar to those reported by Sussex for potato shoots; for the isolated I_1 areas developed only into radial leaves. Yet it is very doubtful whether this indicates that dorsiventrality is induced by the stem apex even in *Epilobium hirsutum*. For in this species, though not in others, we have also obtained radial leaves from the central part of the presumptive area of I_1 and from the central part of P_1 , the youngest actual

leaf, when these regions were not isolated from the stem apex, but were confined at their sides between two vertical cuts which left them continuous with the stem apex towards the centre. In these experiments the stem apex continued to grow and to form leaves, though its growth was sometimes weakened.

At present, therefore, it seems probable that radial leaves can develop in *Epilobium* from some small part of the apical cone of the stem or from the central part of the youngest actual leaf, when such a part, from causes still not clear, grows up from a base which is not large enough to give rise to a dorsiventral leaf. Even a regenerated apex in *Epilobium* may be converted into a typical radial leaf of limited growth if it is extremely small. Also in our potato apices a few small radial leaves developed from small unoccupied areas of tissue that were left over somewhere between the isolated I_1 leaves and the stem. An effect of reduced size of the isolated areas may perhaps account for the radial leaves reported in potatoes by Sussex, though his isolated pieces do not seem from his drawings and description to have been smaller than most of ours. They do seem, however, to have been too close to P_1 for the correct angular position, which may have made a difference. It needs to be further considered whether in *Epilobium hirsutum* reduced size or perhaps weakened growth of the isolated I_1 areas accounts for the radial leaves which developed from them. We hope to publish a fuller account and discussion of our experiments elsewhere.

Degrading Illite and Potash Fixation

SOME clays from Ireland have been examined by X-ray diffraction, and for these soils and some others a relation between potash fixation and clay mineralogy has been established. The clay minerals detected were illite (as defined by Brown¹), vermiculite, chlorite, kaolin and a material which will be provisionally called 'degrading illite'. Some of the soils contained four of these minerals, others only three.

All the minerals except 'degrading illite' are well established*. Diffraction patterns of air-dry clay containing 'degrading illite' show a band from 10 Å. to higher spacings which generally merges with the background at 12–13 Å. and never extends beyond 14 Å. On treating the clay with glycerol, the band disappears giving either (a) lines at 10 Å. and 14 Å. or (b) a line at 14 Å. It has not yet been possible to decide finally between (a) and (b) as the mineral always occurs with illite, which gives a line at 10 Å. Heating the clay to 350° C. for 12 hr. also causes the band to disappear and the intensity of the 10-Å. line is enhanced.

The soils which had been shown by field experiments to fix potash all contained 'degrading illite' while the others did not. None of the other clay minerals showed this simple relationship. It is there-

fore suggested that either 'degrading illite' fixes potash or is related to the actual cause of fixation.

A more detailed account will appear shortly.

I wish to thank Mr. Pierce Ryan, Soil Laboratory, Johnstown Castle, Wexford, for the samples and information about the soils and field experiments.

Paper Chromatographic Separation of the Isomeric Pyridinecarboxylic Acids

In the course of study on the synthesis of the hydrazide of isonicotinic acid, starting with '5^o-picoline', I realized the desirability of providing a control method to follow the separation of the isomeric pyridinecarboxylic acids. Paper chromatography using *n*-butanol-methanol, a system suggested by the very different solubilities of the acids in methanol and water, has been shown to be very efficient for the separation of the three isomers. The substances used in this experiment were the α -, β - and γ -pyridinecarboxylic acids, a mixture of all three, and the mixture obtained by oxidation of '5^o-picoline' with potassium permanganate. The solvent used for the development of the substances, as shown in the accompanying figure, was *n*-butanol-methanol containing 35 per cent water by volume at 20° C. The paper used was T6y8 qualitative filter paper No. 3, 2/40 cm., and the usual ascending method was carried out in a thermostat (18°-20° C.).

After the development, the solvent on the paper strips was evaporated at room temperature, and the yellow well-defined spots were revealed on blue background by spraying with bromocresol purple solution (0.2 per cent in *n*-butanol saturated with water). Uni-dimensional chromatograms obtained in these experiments are shown in the figure. It should be stressed that the R_F values of the isomeric pyridinecarboxylic acids have excellent reproducibility under the experimental conditions described above. However, in the case of the developed mixture of the α -, β - and γ -acids, the R_F value of each isomer is slightly lower.

The R_F values of the isomers decrease in the following order: $\beta > \gamma > \alpha$. It may be noted that this is the same sequence as that observed for the dissociation constants¹ of the acids, as determined in aqueous solution.

(1) α -Pyridinecarboxylic acid; (2) γ -pyridinecarboxylic acid; (3) β -pyridinecarboxylic acid; (4) mixture of α -, β -, γ -pyridinecarboxylic acid; (5) oxidative product of '5^o-picoline' with potassium permanganate

I am very grateful to Prof. N. J. Leonard for advice, and I wish to express my gratitude to Mr. M. Wayaku, director of chemical research, Osaka Gas Co., for supplying '5^o-picoline', α -picoline and 2,6-lutidine.

Paper Chromatography for the Separation of Neutral 17-Ketosteroids in Urine

NEUTRAL 17-ketosteroids have been isolated from extracts of urine by methods too elaborate for routine application^{1,2}. Using chromatography on columns of alumina or silica, quicker methods have been devised³⁻⁷; but these are still somewhat tedious. Separations have been achieved by chromatography on paper previously impregnated with the stationary phase^{8,9}. A technique is here reported for separating the 17-ketosteroids by paper chromatography without any previous impregnation.

The urinary extracts were prepared by the acid hydrolysis of urine followed by extraction with benzene. The benzene extract was washed once with *N* sodium hydroxide, once with distilled water and then dried over anhydrous sodium sulphate. The extract was then shaken with pellets of anhydrous sodium hydroxide⁹ to remove most of the pigment remaining, because it was found that much pigment caused streaking of the chromatograms. Finally, the extract was evaporated to dryness and the residue taken up in a small volume of benzene.

The chromatographic tanks and the solvents used were kept at $34.8^\circ \pm 0.5^\circ \text{C}$. in a thermostatically controlled cabinet provided with an efficient fan. For satisfactory results the atmosphere in the tanks must be in equilibrium with the solvent phases, and the precautions described by Bush¹⁰ were observed. The solvent phases were prepared at 34.8°C . A cyclohexane:20 per cent (v/v) methanol system was used. The Whatman No. 31 paper employed was washed in the mobile phase and dried before use. The extract of urine was applied as spots of approximately 0.5 cm. diameter along a line 14 cm. from one end of a paper strip 40 cm. $\times$ 12 cm. For satisfactory results it was found that the amount of 17-ketosteroid in each spot must not exceed 400 μgm . The paper was equilibrated overnight in the tanks and then run for two hours by the descending technique. The strip was dried, sprayed with a freshly prepared mixture of equal volumes of 14 per cent (w/v) alcoholic potassium hydroxide and 2 per cent (w/v) alcoholic meta-dinitrobenzene, and heated in a stream of warm air for ten minutes.

By this technique six ketosteroid fractions can be detected in extracts of normal male urine. Three of the spots have not yet been identified (approximate R_F values: 0.02, 0.4 and 0.8). One spot (R_F approximately 0.07) appears to be 11-hydroxy-aetiocholan-3 α -ol-17-one and another may be 11-oxy-aetiocholan-3 α -ol-17-one. The most mobile spot (R_F approximately 0.98) is a mixture of aetiocholan-3 α -ol-17-one,

androsterone and perhaps 38-chloro-androst-5-en-17-one. Work is in progress on the further identification of the fractions and the application of the technique to clinical problems.

I would like to acknowledge the financial aid of the Board of Governors of the United Sheffield Hospitals from their Endowment Fund, and to thank Prof. E. J. Wayne and Dr. Arthur Jordan for advice and encouragement.

Quantitative Evaluation of Paper Chromatograms by Infra-red Absorption

THE amounts of materials adsorbed on paper chromatograms can often be estimated directly from measurements of the optical densities of the spots produced by colour-forming reagents. In some cases, it is possible to avoid the colour-forming reaction by measuring the ultra-violet or visible absorptions of the materials themselves. Bellamy¹ has shown that it is possible to examine directly the infra-red spectra of materials adsorbed on paper chromatograms, and it has now been found possible to make quantitative measurements on paper chromatograms by scanning the paper with infra-red radiation of suitable wave-lengths. This method may prove to be particularly useful for substances which do not absorb in the ultra-violet or visible regions and which do not undergo quantitative colour-forming reactions.

In general, the infra-red method is not as sensitive as the ultra-violet method, since the molar extinction coefficients of infra-red bands are usually several hundred times less than those of ultra-violet absorption bands. Irregularities in the paper are more readily observed when scanning with infra-red radiation, and since all papers appear to transmit radiation more uniformly when cut along one direction, it is necessary first to compare paper strips cut both along and across the machine direction. The need to reduce reflexion by wetting with 'Nujol' limits the most useful range for infra-red scanning to about 2,500–1,500 cm^{-1} . Whatman No. 50 papers appear to be most satisfactory for this work.

Preliminary experiments have been carried out with paper chromatograms of amino-acids which have been developed in 50 per cent aqueous ethanol as solvent. Although other solvent systems would give better separations on the paper, this solvent was selected since it could be removed easily from the paper by warming.

A slightly enlarged image of a Nernst filament was projected on to a paper strip 30 mm. wide. The central portion of the illuminated area, 25 mm. $\times$ 3 mm., was re-imaged on to the monochromator entrance slit of a Grubb Parsons S8 single-beam infra-red spectrometer, the paper strip being drawn across the filament image at a uniform rate of 1 in. per minute. An instrumental slit-width of 0.5 mm. was used, corresponding to a spectral slit-width of 25 cm^{-1} at the 1,610 cm^{-1} amino-acid absorption band.

In order to obtain a higher loading and greater sensitivity, the 5.6- μl . samples of the amino-acid solutions were banded uniformly across the paper strips. After developing the chromatograms for several hours, drying off the solvent and wetting with 'Nujol', the strips were scanned in the apparatus.

It has been found that, in the case of bands which have been developed for approximately the same time interval, a smooth curve related the optical density maximum to the weight of material on the paper. Estimations could be made from this curve with an accuracy of about ± 10 per cent. This non-linear relationship is most probably due to the inhomogeneity of the absorbing medium² and to the diffusion of the bands during the development of the chromatogram. Although the latter effect could theoretically be allowed for by measuring the complete area under the optical density curve, background irregularities would make such a method tedious and not very accurate. A much closer approach to a straight-line relationship has been obtained by plotting the weight of material against the product of the optical density maximum and the band-width at half-optical density. Using triplicate samples, it was found possible to make estimations to ± 5 per cent by this method.

Absorption of glycine (G) and alanine (A) at 1,610 cm^{-1}

The upper line in the accompanying figure shows the recording made from a chromatogram of 560 μgm . glycine and 560 μgm . alanine, after development for 15 hr. The lower line represents the transmission of the same paper strip after the 'Nujol' had been washed off with chloroform, the amino-acids washed out with water and the chromatogram strip again wetted with 'Nujol' after drying.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, April 5

SOCIETY OF ENGINEERS (in the Apartments of the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. A. A. Wells: "Brittle Fracture in Steel Structures, with special reference to Liberty Ships".

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY (in the Reynolds Hall, College of Technology, Manchester), at 5.45 p.m.—Prof. Sir Geoffrey Jefferson, F.R.S.: "Thinking and Talking" (President's Address).

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. Helge Larsen: "Alaskan Eskimo Past and Present".

Monday, April 5—Wednesday, April 7

INSTITUTE OF CHEMICAL ENGINEERS (at The University, Birmingham)—Symposium on "Gas Absorption".

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at the Senate House, University of London, Gower Street, London, W.C.1)—Symposium on "Ion Exchange and its Applications".

Monday, April 5—Thursday, April 8

ECONOMIC RESEARCH SOCIETY (at Ashmore Hill, Nr. Leamington Spa), Fourth Annual Conference—"The Scientific Study of Human Work in Industry" (Symposium Secretary: Barbara Murrell, Slaters Cottage, Peppard Common, Henley-on-Thames, Oxon).

Tuesday, April 6

BRITISH OCCUPATIONAL HYGIENE SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 11 a.m.—Conference on "Maximum Allowable Concentrations of Harmful Materials in Industrial Atmospheres".

INSTITUTE OF ELECTRICAL ENGINEERS, MEASUREMENTS SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Scientific Papers.

SOCIETY FOR ANALYTICAL CHEMISTRY, PHYSICAL METHODS GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Meeting on "Mass Spectrometry".

ROYAL SOCIETY OF MEDICINE, PATHOLOGY SECTION (at 1 Wimpole Street, London, W.1), at 8 p.m.—Symposium on "Immunological Problems on Tissue Grafting".

Tuesday, April 6—Friday, April 9

INSTITUTE OF PHYSICS (at the University, Nottingham)—Conference on "The Physics of Particle Size Analysis".

Wednesday, April 7

ROYAL PHOTOGRAPHIC SOCIETY, SCIENTIFIC AND TECHNICAL GROUP (at the Imperial College of Science and Technology, Prince Consort Road, London, S.W.7), at 2.30 p.m.—Symposium on "The Applications of Photography to Research at the Imperial College of Science and Technology".

SOCIETY FOR ANALYTICAL CHEMISTRY (at the Wellcome Research Institution, Ruston Road, London, N.W.1), at 8.30 p.m.—Symposium on "The Comparison of Chemical and Biological Estimation of Drugs in Quantitative Pharmacology". Chairman: Prof. J. H. Burn, F.R.S.

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Dr. G. K. Batchelor: "Heat Convection and Buoyancy Effects in Fluids" (Symposium Memorial Lecture).

INSTITUTE OF MECHANICAL ENGINEERS, INTERNAL COMBUSTION ENGINE GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Discussion on "The Performance of Compression-Ignition Engines under Abnormal Conditions (including Altitude, Temperature, Humidity, Load, Speed or Speed-Variation, Fuel Supply, etc)".

RADAR ASSOCIATION (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 7.30 p.m.—Mr. P. A. L. Harris: "Radar and the Weather".

Wednesday, April 7—Friday, April 9

FARADAY SOCIETY (in the Department of Chemistry, The University, Birmingham)—General Discussion on "The Study of Fast Reactions".

INSTITUTE OF NAVAL ARCHITECTS (on board the Headquarters Ship *Wellington*, Honourable Company of Master Mariners, Victoria Embankment, London, W.C.2), at 10.15 a.m. daily.—Spring Meeting.

Wednesday, April 7—Saturday, April 10

INSTITUTE OF PHYSICS, ELECTRONICS GROUP (in the Cavendish Laboratory, Cambridge)—Conference on "Luminescence" (with particular reference to Solid Inorganic Phosphors).

Thursday, April 8

INSTITUTE OF FUEL (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 4.30 p.m.—Corporate Meeting; 5.30 p.m.—Dr. W. Ides Jones: First Annual Address.

ROYAL SOCIETY OF ARTS, COMMONWEALTH SECTION (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Prof. O. G. Sutton, F.R.S.: "The Meteorological Office and the Commonwealth".

SOCIETY OF CHEMICAL INDUSTRY, MICROBIOLOGY GROUP (at the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W.1), at 6 p.m.—Annual General Meeting; Sir Ian Heilbron: Research at the Brewing Industry Research Foundation.

SOCIETY OF INSTRUMENT TECHNOLOGY (joint meeting with the CONTROL SECTION, at Mansion House, 26 Portland Place, London, W.1), at 6.30 p.m.—Discussion on "Rationalisation of Units for Electrically Operated Servos".

SOCIETY OF DYERS AND COLOURISTS (at the Midland Hotel, Manchester 2), at 7.30 p.m.—Mr. N. W. Yalland: "Physics in the Dyeing, Printing and Finishing Industries" (Eleventh Mercer Lecture).

Thursday, April 8—Saturday, April 10

SOCIETY FOR GENERAL MICROBIOLOGY (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2)—Annual General Meeting.

Thursday, April 8

Scientific Papers.

Friday, April 9—Saturday, April 10

Symposium on "Autotrophic Micro-organisms".

Friday, April 9

BIOCHEMICAL SOCIETY (in the Department of Biochemistry, University New Buildings, Edinburgh 8), at 11 a.m.—Scientific Papers.

ASSOCIATION OF APPLIED BIOLOGISTS (in the Metallurgy Lecture Theatre, Imperial College, Prince Consort Road, London, S.W.7), at 11 a.m.—Annual General Meeting; 2.30 p.m.—Dr. E. C. Bates-Smith: "Objectives in Food Research".

INSTITUTE OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Paper on "The Control and Observation of Dust at Pneumatic Chassis and Portable Abrasive Wheels". Part 1—Mr. A. T. Holman and Mr. E. B. James: "Dust Control Systems". Part 2—Mr. W. B. Lawrie: "Dust Observations".

ROYAL SOCIETY OF MEDICINE (at 1 Wimpole Street, London, W.1), at 8.30 p.m.—Dr. M. G. Candau: "The Role of W.H.O. in International Health Work".

Friday, April 9—Saturday, April 10

BOTANICAL SOCIETY OF THE BRITISH ISLES (at Church House, Great Smith Street, Westminster, London, S.W.1), at 10.15 a.m. each day.—Conference: "The Species Concept in its Relation to the British Flora".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT ANALYST (with a university degree or A.R.I.C., and preferably with experience in the analysis of food and drugs)—The County Medical Officer of Health, East Chiff County Offices, Preston, quoting "Assistant Analyst" (April 10).

ASSISTANT COAL SURVEY OFFICER (with a good honours degree or equivalent in chemistry or fuel technology, and preferably with experience in industry, in laboratory control, and in the critical assembly of scientific data) at the Coal Survey Laboratory, Sheffield—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT764 (April 10).

ENGLISH ELECTRIC COMPANY RESEARCH FELLOW (graduate in engineering or applied science, and some experience in aircraft engineering practice) in AERONAUTICS, at the University of Glasgow—The Secretary of the University Court, The University, Glasgow (April 10).

PROFESSOR AND HEAD OF THE DEPARTMENT OF AERODYNAMICS—The Principal, The College of Aeronautics, Cranfield, Bletchley, Bucks (April 13).

SENIOR LECTURER IN MECHANICAL ENGINEERING, LECTURERS (2) IN MECHANICAL OR CIVIL ENGINEERING, A LECTURER IN ELECTRONICS, A LECTURER IN ELECTRICAL ENGINEERING, A LECTURER IN PHYSICS, AND DEMONSTRATORS IN PHYSICS OR MECHANICAL ENGINEERING OR ELECTRONICS, at the Royal Military College of Science, Shrivenham—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting S 4807/64 (April 15).

UNIVERSITY PROFESSOR OF PHYSIOLOGY at Patna University, India—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (April 17).

ASSISTANT LECTURERS (2) IN PSYCHOLOGY—The Registrar, The University, Manchester (April 21).
